Bell's name has become a common word in neurology. One thinks first of Bell's palsy. When Bell began his work, utter confusion prevailed. It was thought that the direction of nerve forces was reversible, that many small nerves were equivalent to one larger one, that the two nerves are given to the face lest, by the accidental division of one, the face should be deprived of nervous power altogether, that if one nerve of the face were cut the remaining nerve would bestow both sense and motion, though in a diminished degree. This was the authority on which surgeons were wont to divide one or other nerve of the face in the attempt to cure the *douloureux*.

"It is very frequent," he says, "for young people to have what is vulgarly called a blight, from exposure to cold, by which is meant a slight palsy of the muscles on one side of the face. Inflammation of glands seated behind the angle of the jaw will sometimes produce this. Before these observations, it would have been said, that paralysis could not be so produced, because the parts are plentifully supplied by the branches of the fifth nerve, that the disease must be in the brain."

He appends numerous case reports of this condition and emphasizes the good prognosis.

#### THE EXTERNAL RESPIRATORY NERVE OF BELL

One hears also of the "nerve of Bell." Bell was tremendously interested in the play of muscles involved in respiration, speech and expression. "The nerves on which the associated actions of voluntary and excited respiration depend, arise very nearly together."

He says (1821) "The following are the nerves to be enumerated as respiratory nerves, according to their functions: 1 Par vagum, the eighth of Willis, the pneumo-gastric nerve of the modern French physiologists. 2 Respiratory nerve of the face, being that which is called the *portio dura* of the seventh. 3 Glossopharyngeal. 4 Superior respiratory nerve of the trunk, being that which is called spinal accessory. 5 Great internal respiratory nerve, the phrenic or diaphragmatic nerve of authors. 6 The external respiratory nerve." (In "The Anatomy and Physiology of the Human Body," he says, of the fifth cervical nerve, "This nerve I call the External Respiratory Nerve.") This has a similar origin with the preceding nerve. It comes out from the cervical vertebrae and is connected with the phrenic nerve. It runs down the neck, crosses the cervical and axillary nerves, passes through the axilla and arrives on the outside of the ribs, to supply the serratus magnus anticus, which, it is scarcely necessary to observe, is a muscle already supplied by nerves coming out between the ribs, from the system of regular nerves.

#### BELL'S SIGN

The title of the paper in which this sign was described is "On the Motions of the Eye, in Illustration of the Uses of the Muscles and Nerves of the Orbit" (1823). This paper is a masterpiece. It is crammed with observations, so briefly, so clearly described that it ought to lie near the hand of every author and editor of a medical paper. I shall quote from this paper:

There is a motion of the eye-ball, which, from its rapidity, has escaped observation. At the instant in which the eye-lids are closed, the eye-ball makes a movement which raises the cornea under the upper eye-lid. If we fix one eye upon an object, and close the other with the finger in such a manner as to feel the convexity of the cornea through the eye-lid, and shut the eye that is open, we shall feel that the cornea of the other eye is instantly elevated, and that it thus rises and falls in sympathy with the eye that is closed and opened. This change of the position of the eye ball takes place during the most rapid winking motions of the eye-lids. If the eye-balls were to remain without motion, the margins of the eye-lids would meet in such a manner on the surface of the cornea, that a certain portion would be left untouched, and the eye would have no power of clearing off what obscured the vision, at that principal part of the lucid cornea which is the very axis of the eye.

He supplemented these observations with experiments on monkeys, in which he cut the superior rectus muscle, the superior oblique muscle and the inferior oblique muscle. "By these experiments it is proved, first, that the division of the oblique muscles does not in any degree affect the voluntary motions by which the eye is directed to objects. Secondly, that the division of the recti does not prevent the involuntary motions. When the eye is at rest, as in sleep, or even when the eye-lids are shut, the sensation of the retina being then neglected, the voluntary muscles resign their office, and the involuntary muscles draw the pupil under the upper eye-lid. This is the condition of the organ during perfect repose."

While conducting the experiments on the oblique muscles, he appended a weight to the tendon of the superior oblique, which he noted descended during the contraction of the inferior oblique. He recognized not only the principle of reciprocal innervation but demonstrated it experimentally and observed, "There must be particular and appropriate nerves to form this double bond to cause them to conspire in relaxation as well as to combine in contraction."

#### MUSCLE SENSE

While there had been, as Bell later discovered, speculation regarding sensation in muscles, it had not been placed on a parity with other modalities of sensation or expressed as a physiologic concept. He says:

It will presently appear that the motor nerves are not suitable intermediaries between them and the sensorium. Between the brain and the muscles there is a circle of nerves, one nerve conveys the influence from the brain to the muscle, another gives the sense of the condition of the muscles to the brain. The lower degree of sensibility to pain possessed by the muscles, and their insensibility to heat, is no argument against their having nerves which are alive to the most minute changes of action in their fibres.

#### BELL AS TEACHER AND CLINICIAN

When one considers the methods by which Bell contributed so richly to neurophysiology, one senses his greatness. Experiment is one of the most helpful tools of the physiologist, yet Bell with remarkable

prescience drew most of his facts from anatomy. He had a remarkable facility of coordinating structure with normal activity. To Bell, anatomy was a living subject, with it he salted his clinical observations.

Gentlemen [he says], wise men pursue some determined object. I may have erred in having more than one. I confess it has been my desire to combine the philosophy of the profession with the practice of it, because I believe them to be necessary to each other, and both to the true respectability of the individual.<sup>9</sup> For all real improvements in our science are suggested by the occurrences in practice. None will hesitate to say that it is our duty to observe accurately when an accident may be converted into an experiment. This poor man was tossed by a bull, the horn went in here, at the angle of the jaw, and he hung suspended upon it until, the integuments before the ear giving way, he dropped. And you cannot resist the conviction that the remaining sensibility is owing to the entireness of the branches of the fifth pair, which come out through the orbit, and through the upper and lower maxillary bones, whilst the loss of motion has resulted from the tearing of the portio dura.

The consummate art with which he presented a case is in evidence in the following:

Patient with Dr. Marshall Hall. Apparently about sixty, his intellect I ought to say entire, since he was complimentary, but with a manner singularly in contrast with any thing like interest. All the lower part of his face is relaxed in paralysis, the lips hanging loose, speaking consequently very imperfectly. The same inactivity and want of expression in his nostrils. He has lost the left eye, and he has to hold up the eyelid of the right eye with the finger to see us. He closes his jaws very feebly, and there is a sensible defect of action in the masseter and temporal muscles of both sides. His complaint commenced about three years ago in an extraordinary weariness of the jaw, while at dinner, and which now continues. The taste is natural, and the sensibility of the tongue entire, but the action of the tongue feeble, so that he must use his finger sometimes to assist it in moving the morsel. He cannot spit out. There is a complete paralysis of the velum and uvula, so that when he drinks the fluid comes out through his nose. He has great difficulty in swallowing, that is, in propelling the morsel from the dorsum of the tongue into the pharynx. Thus, at present, is the most serious and pressing evil.

One more case history I will give, since it may be the first recorded case of spontaneous, hyperemic atlanto-axoid dislocation, nasopharyngeal torticollis, or Grisel's syndrome, the nature of which he recognized.

A patient, who had a deep ulcer in the back part of the throat, was seized with symptoms like those of apoplexy. These symptoms continued for two hours. At this time the patient's head fell suddenly forward, and he instantly expired. On dissection, it was found that the ulcer had destroyed the transverse ligament, which holds the process of the dens in its place. In consequence of the failure of this support, the process was thrown back so as to compress the spinal marrow. The parts are preserved in my collection (fig. 3).

It is interesting not only to know what a man has done but to seek that imponderable quality in him that will answer the query: How did he do it? Obviously Bell did not idle away much of his time. He had his own idea of relative values and spent little effort in what is often called "playing politics." He spoke of his friend as the "sarcastic Mr. Abernethy" and advised young gentlemen who went to the College of Surgeons in order to pass to "keep to old theories." Very possibly Bell was not a man we should have loved. Aristotle said, "Men who desire to learn, must previously know how to doubt, for science is only the resolution of previous doubts, but he who does not know the knot, is unable to untie it." Bell knew the

knot. He had an idea and pursued it like one possessed. As Stevenson has said, "When a man begins to sharpen one faculty and keeps on sharpening it with tireless perseverance, he can achieve wonders." That is, he worked. He had faith in himself and "never blamed a pear tree for not bearing plums."

Our interest in men should not remain wholly static. Just as their achievements reach into the future, so do their personalities bear fruit. In closing, let me leave with you some thoughts expressed by this great man:

Since I am about to describe all the niceties and difficulties of the operation for Strangulated Hernia, I must in the first place declare that it requires more knowledge and experience to decide upon the right time of performing it, than to do it well.<sup>10</sup>

The viscera of the abdomen perform functions the most independent of the will and over which the mind has no control.

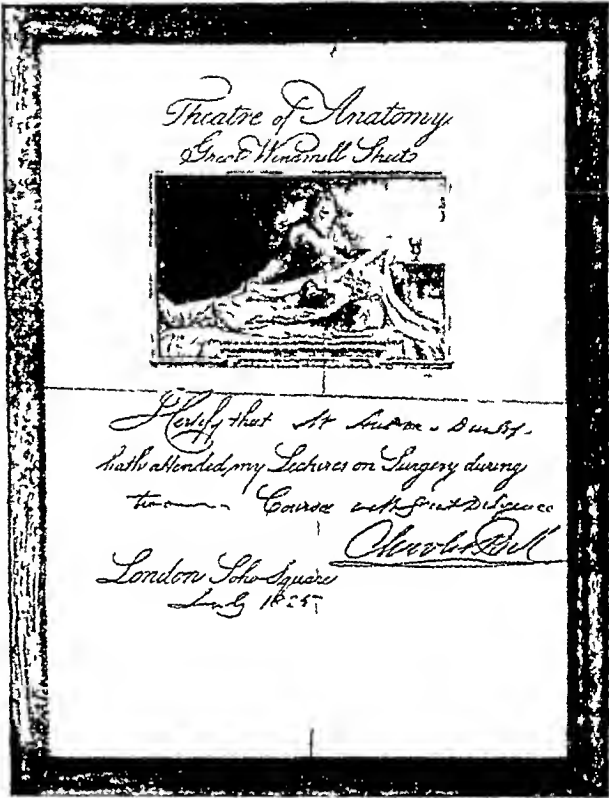

Fig. 3.—Certificate issued by Sir Charles Bell to one of his students (see parenthetical note to figure 1).

Indeed it appears to be one of the happiest provisions of Nature that these functions of vital importance should be withdrawn from the governance of the mind.

I acknowledge that in the dissecting room the student learns the elements only, that to let loose upon the world a young surgeon, whose education has been confined to dissection, is like arming a man bereft of reason.<sup>10</sup>

A public operation, where young surgeons are attending, ought to be done not only in a manner that shall be safe to the individual who suffers but exemplary to those who are to learn.

These are the authors who avoid plainness, as if it were meanness, who are studious of hard words, as if they constituted the perfection of science. It is their trade, it is their

<sup>9</sup> Bell, Sir Charles. Illustrations of the Great Operations of Surgery, Trepan, Hernia, Amputation, Aneurism and Lithotomy. London: Longman, Hurst, Rees, Orme, and Brown, 1821.

<sup>10</sup> Bell, Sir Charles. A System of Operative Surgery, Founded on the Basis of Anatomy. Hartford: Hale and Hosmer, 2, 1812.

mystery to write obscurely," and fully sorely does the student feel it

Haller remembers, that while he was lying in a bad fever, he suffered so much from the pulsations of the carotid artery within the skull that his head was lifted from his pillow at every stroke. I wish he had said "seemed to be lifted from the pillow at every stroke"<sup>11</sup>

Did I ever tell you [he wrote to his brother] I was offered £100 a year for the use of my name? But I thought they would dirty it, so I would not lend it. It was to stick on the first leaf of a journal

You tell me to cultivate men, I wish you had said, "to be industrious and cultivate a proud spirit of independence"<sup>12</sup>

You say that no man can rise into great practice without being in company or, rather, say society. I do not agree with you. Pardon my vanity when I say that my business comes through, and will increase by, different means. My patients are now of a proper class, whom I know nothing of. They come from my character, and are retained by finding relief by being treated with attention and kindness. My means of being known are through my books and pupils. I retain my consequence by preferring science to practice.<sup>13</sup>

I have referred to a patient who had been subject to tic douloureux, and who had been more than once cured of his pain by croton oil [Bell's remedy, introduced from India in 1825], having died last autumn. There was no disease in the nerve, but ulceration was found in the mucous coat of the ileum. But then it is said in the report conveyed to me that he had been too powerfully dosed with this medicine. I take the facts either way, the ulceration was the cause of the tic, or the ulceration was occasioned by the medicine. In this last supposition, we have the important admission, that croton oil improperly used, will act on a portion of the mucous coat to the formation of ulcer. Could we depend on this reasoning, it would explain how the better regulated administration of the medicine did, in very many cases, affect a portion of the intestine to the removal of morbid irritation there.<sup>12</sup>

I cannot refrain from giving a quotation Corson discovered in the works of Charles's celebrated brother John, for it applies as truly now as it did then

When your opinion is called for, pronounce it boldly, and say, if you think it right to say so, "This limb must be cut off." But when you are prevented by officious relatives or if the patient should refuse his consent, when the accidents of the case interrupt you, or you are in a confused or dangerous camp, where operations cannot be done, then do what remains of your duty—not with ill humor of a man thwarted in some little view, or smarting under the sense of a disappointment or affront—set yourself heartily and kindly to save your patient's limb and his life.<sup>13</sup>

**Medical Social Problems**—One can still find physicians who take the view that medical social work concerns only the poor and friendless. They forget that such work is not concerned with charity or spiritual welfare, as is that performed by the church. The social problems in private practice are as numerous and frequent as in hospital practice and are often more complex and difficult to correct. This is because the higher the social order of the patient, the more complicated the social issues and intricacies of life are apt to become. To appreciate this, one only has to think of the greater complexities arising in the life of a person with servants, children in private schools, many friends and multiple social, professional and business obligations, as contrasted with the life of a day laborer yet both may be confronted with basically the same medical social problems—Minot, G. R. *Medical Social Aspects in Practice*. *Arch. Int. Med.* 54: 1 (July) 1934.

## CLINICAL FEATURES OF EPIDEMIC (ST LOUIS) ENCEPHALITIS

R. A. KINSELLA, M.D.

AND

G. O. BROWN, M.D.

ST. LOUIS

The epidemic of acute encephalitis that made its appearance in the St. Louis area in the late summer of 1933 marked the first appearance in the United States of this disease in epidemic proportions. It is known that isolated cases appeared in many other localities, and a small group of cases appeared in Paris, Ill., in the preceding year. Epidemics of encephalitis had been occurring in Japan for nearly ten years, and descriptions of the Japanese cases seemed to fit the clinical picture of the St. Louis disease. But it is now thought that the Japanese disease was due to a virus immunologically different from the virus recovered in the St. Louis cases. This consideration will convey an impression of the surprise and uncertainty which clinicians felt when confronted with this clinical picture in the days before the disease became widespread and recognition became easy.

The symptoms of encephalitis were, of course, easy to recognize, but the previous epidemic of lethargic encephalitis left impressions that were not recalled by the present disease. Apart from lethargic encephalitis, there had occasionally been seen a solitary case of encephalitis during the past ten years, which may, perhaps, have been identical with the epidemic encephalitis of the St. Louis type, but such diagnoses were considered to apply to cases of doubtful nature and no pathologic studies had pointed to a similar origin.

It is our purpose in this paper to point to the most common symptoms and signs and to the most striking combination of these, so that if and when the disease reappears physicians may be familiar with these salient features and take steps to organize a cooperative enterprise for the study and control of the disease in their respective communities.

Known to be caused by infection by virus, this disease has as yet not revealed its mechanism of origin and transmission, and there is much still to be done by epidemiologists, just as there is still much to be learned about the immunology and treatment.

It has been customary in the past to emphasize the feature of tropism or the selective aggressiveness of virus. Thus, the virus of influenza is spoken of as having a pneumotropic tendency, the virus of rabies a neurotropic activity, and so on. There is no doubt that the virus of St. Louis encephalitis had an almost exclusively neutropic activity, but enough involvement of organs remote to the nervous system was observed to indicate that the virus was capable of producing damage in other parts. The portal of entry into the body is not certainly established, but the experimental evidence points to a probable route through the upper nasal passages directly into the brain. The lesions in the lungs and in the duodenum, though not common, have been regarded as due to migrations of the virus already in the body rather than to reactions produced at places of entry.

From the Department of Internal Medicine, St. Louis University School of Medicine.  
Read before the Section on Practice of Medicine at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

The present description is based on observation of 215 cases seen at the Firmin Desloge Hospital and St Mary's Hospital. In one of these hospitals the patients were subjected to one form of treatment, in the other, many forms of treatment were employed, because the patients were cared for by many physicians working independently. In both instances a busy house staff struggled gloriously to keep records and observations up to a standard.

Standing at a distance, one may now visualize a disease acute, febrile and encephalitic from beginning to end. Other diseases may have encephalitic features. Malaria, syphilis and typhoid may present signs of irritation of the brain, but this disease was always and chiefly encephalitis.

The onset was usually abrupt, even though one or two days may have been required to establish prostration. The onset was with pain in the front and top of the head, dull, constant, compelling and often stupefying pain. The fever was prompt in its appearance. The conjunctivae were reddened and the neck was almost invariably stiff. This should be visualized as the picture, even though minor variations may detract from the accuracy of the portrayal.

Thus, for example, some cases seemed to have presented a period of upper respiratory infection or even gastro-intestinal disorder such as diarrhea, for several days or even weeks before the onset of encephalitis. But the average patient had no preceding illness.

The infection seemed to declare its predilection for the brain at once. Fever continued to attend the development of the intracranial lesions, and the peripheral manifestations of these lesions completed the clinical picture. The manifestations of the disease as it affected the brain were both psychiatric and neurologic. After a period of twenty-four hours of severe headache the patient soon betrayed the severity of the lesion in the brain. He settled back in dull, stuporous discomfort, awaiting the abatement of the inflammation, or became confused, mildly delirious and, finally, comatose.

Added to this were the manifestations of neurologic nature, patterned by the extent and intensity of the development of cerebral inflammation. The suppression of cutaneous reflexes was conditioned by the degree of mental occlusion. The existence of abnormal responses to stimulation, such as the Babinski and kindred signs, was encountered very frequently. At the same time cranial nerve involvement was infrequent and interference with functions such as swallowing was found only in the fatal types. Abnormal pupillary reactions to light as well as generalized muscular spasticities and tremors with attending aching of these areas were the usual occurrence.

If abdominal pain, nausea and vomiting were complained of, these complaints were not a matter of surprise, occurring as they did in about 20 per cent of the cases. Perhaps the inflammation of the duodenum occasionally seen at autopsy has an explanatory connection.

An influenza-like pneumonia was common in all the fatal cases. Retention of urine was naturally frequent in a disease in which stupor was so common.

The fever was not of a type that lends itself to popular description. In any epidemic, the cases that terminate early most likely present the purest expression of febrile effects. If this is true, the fever curve of epidemic encephalitis spans four or five days, is sustained and is without remissions. In many mild cases, however, remissions occurred with some relief from symptoms as well followed in a few hours by the pre-

viously high temperatures. The peaks usually reached levels of 103 to 105 F. In those cases in which the disease and its fever were protracted, it still seemed possible to detect a tendency to relief at the fourth or fifth day.

In this connection the leukocytosis is interesting. In the simple cases of short duration, no disturbance was noted in the number and kind of leukocytes. But in the cases that were prolonged, leukocytosis was common, the commonest level being between 10,000 and 15,000 cells per cubic millimeter. Even at this level there were no significant qualitative changes. Since so many of the patients were adults between 50 and 70 years of age, with numerous concomitant infirmities and disorders, this irregularity in the number of leukocytes may perhaps be taken as representing the influences of factors other than those due to the encephalitis.

The other examination made in the laboratory which is of diagnostic meaning was the examination of the spinal fluid. This fluid was usually under little or no increase in pressure. The globulin was present in the spinal fluid in 70 per cent of the cases in this series. The large majority of cases showed increases in the amounts of sugar to levels between 60 and 100 mg. Nearly all fluids presented an increase in cells, the greatest number showing counts between 50 and 100 cells. Ninety per cent of these cells were lymphocytes. In a series of ninety-nine cases so examined, a tabetic gold curve was encountered in eighty-seven cases. There were no other laboratory tests of importance.

The average patient was well in ten days. In the comprehensive report of the Metropolitan Health Council, covering a study of 986 patients who were treated in hospitals, recovery is described as surprisingly rapid and complete. While the devastating sequelae not infrequently seen after lethargic encephalitis did not follow this type of encephalitis, nevertheless a survey made by one of us (G O B) revealed a surprising amount of minor disabilities, which in the vast majority of cases did not prevent the patient from returning to work or to school. Among their disabilities, muscular instability, "shakiness" and a tendency to headache were the most common.

In children, the disease presented a milder display of symptoms and signs, and the death rate was lower. Occasionally, however, a fulminating disease, terminating fatally in forty-eight hours, was seen. In general, the disease was as easily recognized in children as it was in adults.

As for differential diagnosis, it was emphasized in the beginning that, if the entire pattern of the disease was considered, it would be seen that the chief confusion lay in differentiating an encephalitic "episode" or "phase" of a disease like malaria, typhoid or syphilis from this type of encephalitis. The data obtained from the laboratory, viz, the finding of plasmodia, the occurrence of a positive test for syphilis or the discovery of a positive Widal test or blood culture, were the points on which differentiation rested. It would be more difficult to separate this disease from lethargic encephalitis. However, in all cases the serum of a patient with this type of epidemic encephalitis will contain protective substance against the lethal dose of known infected material when injected simultaneously in the cranium of a white mouse. This is the final and best test. By this test this disease has been said to be distinguishable from the disease that occurred in Japan.

The death rate in the 786 cases studied by the Metropolitan Health Council, including the 215 cases

embraced in this report, was within a decimal point of 20 per cent. A study of the mortality rates in different groups is valuable in discussing the treatment.

Many types of treatment were employed. In private hospitals particularly patients were treated according to the various concepts of the problem which many and various physicians entertained.

Besides symptomatic relief, patients received mercurochrome intravenously, transfusions of blood, and even intravenous injections of spinal fluid. The items of treatment that were constantly indicated were: 1. Spinal puncture for diagnostic purposes and for the relief of headache. 2. Administration of fluids, usually under the skin. 3. Administration of liquid food, by nasal tube, if necessary. 4. Absolute rest and, if necessary, sedation by morphine. The best treatment consisted in placing the patient in a darkened room, free from noise and free from too frequent ministrations by nurses or doctors. Then the essential features of treatment as outlined were observed. In a series of 129 cases treated exclusively after this plan at Firmin Desloge Hospital, the death rate was only 12 per cent, and the age distribution and the number of severe cases in this group were identical with the other groups in the total number of 786 referred to.

The chief lesson we learned of the treatment of epidemic encephalitis was that the lowest death rate attended the most conservative treatment.

Beaumont Building

#### ABSTRACT OF DISCUSSION

DR J P LEAKE, Washington, D C. I hardly think that this can be just the same disease as the encephalitis of von Economo, which was prevalent from 1918 to 1923. It is a more acute affair and has much less in the way of sequelae. In the outbreaks in Japan, particularly those of 1912, 1919, 1924 and 1929, physicians are indebted chiefly to Dr Webster and his colleagues of the Rockefeller Institute for neutralization results. It is true, as Dr Kinsella said, that the neutralization tests were negative with serum obtained from Japan, which would indicate that these Japanese cases were of possibly a different strain. However, the clinical and epidemiologic characteristics of those epidemics are so nearly the same as what occurred within the St. Louis area and radiating from there, that that result will have to be taken under consideration. Dr Armstrong of the National Institute of Health has also conducted neutralization tests and will not report until he has completed and checked from what source the serum comes. The Japanese serum did not come in question here. It is possible that serum obtained from such a distance may lose its neutralizing properties. Dr Kinsella has spoken of a remarkable low death rate, 12 per cent. It may well be that that was due to careful handling and, as he says, absence from too much therapeutic interference. It would seem that the results as a whole in St. Louis might have been influenced by the way the cases were handled. About 95 per cent of all the cases in the epidemic in St. Louis City and County, 1,100 cases, were hospitalized. That is due to the recommendations and assistance of Dr Brady and Dr Sante, the assistant health commissioner of St. Louis City, and health authorities of St. Louis County and Dr Musser of the state board of health. The isolation was only for three weeks, which, although cases might be considered a source of spread of infection, as the epidemiology showed, was not of great importance. There were relatively few multiple cases in one household. Still it did keep the patients quiet and under good medical attention. The largest death rate from the epidemic in Japan was 50 per cent in 1924 and 57 per cent in 1927. In the epidemic in Paris, Ill., the year before the St. Louis epidemic, the death rate was 37 per cent. In St. Louis as a whole it was only 20 per cent. It is possible that low result was due to that method of handling. The great proportion of the cases of von Economo did

present some sequelae and those sequelae were largely of an organic type. Parkinsonian or behavior disorders were prominent. Those things didn't occur after the epidemics in Japan, St. Louis and Paris, Ill. It is too early to speak with great certainty about the St. Louis epidemic. In going over the Paris, Ill., cases fifteen months later, however, there was a notable absence of such sequelae. Those that Dr Kinsella mentioned were more of the neurasthenic type. Only 18 per cent of the cases in Yokohama, Japan, showed any sequelae within twelve months.

## ENDOCRINE DWARFISM

WILLIAM ENGELBACH, M.D.

AND

ROBERT L. SCHAEFER, M.D.

DETROIT

The problem of diagnosis and treatment of statural undergrowth, or dwarfism, rightfully belongs to the general practitioner and pediatrician. One has but to study the normal growth increment curve in the human

Fig 1—Optimal height weight curves

being for this proof. It testifies to the fact that approximately 50 per cent of the total growth has been attained at the age of 3 years. Its increasing plateau diminishes rapidly as adolescence or sex maturity is attained. It logically follows that diagnosis and adequate treatment during the infantile and early juvenile periods should give greater therapeutic results.

There is an abundance of experimental evidence that the factor concerned in somatic growth is produced by the eosinophilic cell of the anterior lobe of the hypophysis. By this is meant that every structure of the body, from an individual cell to the constitutional whole, is involved.

The three postulates of hormonology, the therapeutic side of endocrinology, are completely fulfilled in the

This work was initiated previous to the death of Dr Engelbach Nov 22, 1932.

anterior lobe of the hypophysis The first is that of gigantism in which the hyperfunction occurs before adolescence, or epiphyseal closure, resulting in proportionate gigantism The second is that of acromegaly due to a similar hyperfunctioning adenoma that occurs after adolescence and, consequently, after epiphyseal closure The overgrowth, then, does not result in a statural increase in height but effects those bones which derive their growth from the periosteum, such as the bones of the face and vertebrae

Evans and Long in 1921 first recognized and demonstrated this hormone Their preparation was a saline

capable of furnishing an adequate diet The individual protocols are detailed in our preliminary report<sup>2</sup> In the gross, their histories over a protracted period of time suggested a stationary or very minimal growth To reemphasize, this table also reveals that they were under a control period of from two to six months, during which time no increase in height was noted except in case 5, and this was only half an inch To rule out the specificity of thyroid extract as being capable of producing growth, four of the seven patients exhibiting signs of hypothyroidism were given thyroid extract to tolerance during this period of control The

growth hormone than those animals dwarfed in the same manner and treated with the growth hormone alone

Patients 1 and 2 exhibited no further growth after their initial stimulation, although treatment was carried on for a considerable period of time. They displayed a normal or advanced roentgenographic study of osseous development. They were at or approximating adolescence or sex maturity. This study of the normal growth increment curve reveals that epiphyseal closure and sex maturity are coincidental phenomena at this epoch of life. This suggested that there is an antagonism between the sex and growth hormones of the anterior lobe of the hypophysis. This belief is further substantiated clinically in patient 2, in whom normal rhythmic periods had been established at 12 years and continued to 15. The administration of this substance produced two periods of amenorrhea. In an additional case, not cited in the table, a male dwarf, aged 32, displaying normal libido and potentia, became temporarily impotent during his period of treatment. It is our theory that epiphyseal closure is dependent on gonadal development and consequent hormone function.

In case 6 there was a moderate genital aplasia, and roentgenographic study for osseous development showed retardation. His growth of 27 inches was termed a favorable response, but further cooperation could not be obtained and treatment necessarily was discontinued.

Four cases outlined in table 2 have been under treatment continuously for over a period of from fourteen to fifteen and one-half months. The increase in statural growth was from 3.3 to 6 inches. All of the patients received thyroid extract in therapeutic doses together with the growth substance with the exception of patient 7, who received the growth substance alone.

Fig 2 (case 3)—Condition of knee A before treatment, B fifteen and one-half months after treatment

COMMENT

If one bears in mind the control period of observation without treatment and the history of a lack of growth over a long period of time, it is not unwarranted to assume that the therapeutic response has been due to the specific medication administered. These four cases all demonstrated a definite retardation in roentgenographic studies for osseous development, the delay vary-

ing from one to four years. Nine out of sixteen cases observed, in addition to the delay in osseous development, presented another significant roentgenographic finding. This has been previously termed chondro-epiphysitis. It is more or less generalized, involving from a few to all of the developing epiphyses and osseous centers. This is characterized by a fuzzy,

Fig 3 (case 3)—The ankle A before treatment B after treatment

ragged, poorly outlined appearance together with decreased bone density. Treatment produced an advance in osseous development, as can be seen in figure 2. The abnormal appearance of these developing osseous centers has almost approached the normal. Figure 3 was diagnosed roentgenologically as Kohler's disease, a similar type of disturbance involving the scaphoid and tarsal bones of the ankle. The comparative roentgenograms after treatment revealed a complete return to normal. This suggests the possibility that Köhler's disease, Osgood-Schlatter's disease, Perthes' disease and similarly allied conditions showing these chondro-epiphyseal changes in the growing child are not inflammatory in character but are due to an incretory imbalance.

These cases have recently displayed little or no further growth during a period of from three to five months, although the same dosage and number of injections were employed. This was rather disconcerting, but biologic assay revealed that the material we had been using over this period of time had lost its potency entirely. We are prone to view this as additional evidence that previous stimulation was entirely specific and, in addition, that this extract is not thermostable. It should further serve as another period of control without treatment.

SUMMARY

- 1 To secure results, diagnosis and treatment of dwarfism should be made early.
- 2 The extract employed does contain the growth hormone.
- 3 The work of Smith indicates that thyroid extract is a valuable adjunct in this form of treatment.
- 4 The cases giving the most favorable response displayed a delay in roentgenographic study of osseous development.

5 Sex maturity and epiphyseal closure, coincident phenomena, preclude further stimulation of statural growth

6 The chondro-epiphyseal changes described are not uncommon in this type of individual, and it is suggested that they are not inflammatory but endocrine in origin

### ABSTRACT OF DISCUSSION

DR ROY G. HOSKINS, Boston Such a study as this is beset with difficulties. The first is the nuisance of the needle. Another is the uncertainty of potency and composition of the growth preparations now available. A third is the propensity of growth to occur in spurts at different ages in different individuals. The interpretation of the data necessitates consideration of this growth spurt—the possibility that it has been delayed and would have occurred spontaneously without any medication whatever. As a revulsion from the disgraceful shotgun pharmacy that has been employed a great deal in endocrinology, the feeling has grown up that an attempt should be made to reacquire some sort of scientific chastity and use only one hormone at a time. But in the treatment of growth deficiency by pituitary extracts, the thyrotropic and the supra-renalotropic principles must be used in addition to the growth hormone. Insistence on single gland medication in such cases is a sort of fetishism. In the practical management of these cases, different preparations that may be effective should be used. That is indicated, among other things, by the fact that after a while a resistance to any one preparation may be built up. The patients cease to react so well, or they may cease to react at all to the growth preparation. The explanation probably lies, as demonstrated, in new work at Collip's laboratory which suggests that the use of these hormone preparations induces in the body the production of antihormone substances, hence, after a time the material ceases to be effective. In cases such as Dr. Schaefer reports it is desirable when "growth extract" begins to be ineffective, to shift to thyroids and then

use of the growth hormone, as does the sugar of the blood with the use of insulin. Recent work in Collip's laboratory shows also that there is a very important relationship of the "growth hormone" to calcium metabolism. Speaking now from the standpoint of endocrinology in general, I hope that Dr. Schaefer and others pursuing this type of research will have the time and the inclination to make careful studies of the psychology of the situation. The human being is not

Fig 5 (case 5)—A youth, aged 18 years 6 months. Measurement of head 21 inches (22.4 optimal), chest 29.5 inches (34.1 optimal), abdomen 29.7 inches (28.4 optimal)

Fig 4 (case 7)—A girl, aged 7 years 4 months. Measurement of head 18.5 inches (20.3 optimal), chest 19.5 inches (22.7 optimal), abdomen 19 inches (20.5 optimal)

perhaps to glycerine extract of suprarenal cortex. The underlying physiology of Dr. Schaefer's study is important. The work of Lee is making it appear that the pituitary growth hormone is the regulator of protein metabolism *par excellence*. The nonprotein nitrogen of the blood seems to vary with the

merely a collection of viscera and of interest, therefore, only as a physiologic specimen. The thing that gives meaning to this collection of viscera is the personality of the individual. The most difficult phase of endocrinology and one that now especially demands serious research is the effect of various hormones on personality and mentality.

DR MURRAY B. GORDON, Brooklyn. In a recent study of about 1,000 children from the point of view of mentality, there were 529 with endocrine disturbances, and of these forty-seven were instances of anterior pituitary deficiency of growth. The children in this group were the most intelligent of the entire endocrine group. Nineteen per cent of those with anterior pituitary deficiency showed mental retardation, as against 97 per cent in childhood myxedema and 36 per cent in other pituitary conditions. In a developmental study, normal children with anterior pituitary deficiency of growth began teething at 93 months, walking at 1506 months and talking at 1697 months. In other words, a child with anterior deficiency of growth and normal mentality will teethe, walk and talk later than one with adipsogenital dystrophy and thyropituitary obesity but probably not earlier or later than one with hypothyroidism. A child with mental retardation and anterior pituitary deficiency will teethe and walk later than one with any other endocrine condition with exception of childhood myxedema and marked instances of hypothyroidism. There were several points not covered in the differential diagnosis between hypothyroidism and anterior pituitary deficiency of growth. In hypothyroidism, the outstanding features are delayed carpal development, low basal metabolic rate and high blood cholesterol. In anterior pituitary deficiency the specific dynamic action is lowered or absent, the basal metabolic rate may or may not be lowered, depending on the involvement of the thyrotropic hormone, and blood uric acid and blood chlorides are high in values. With regard to the general treatment of anterior pituitary deficiency of growth I must confirm the statement of Dr. Schaefer and Dr. Hoskins that how much of the increase in growth following combined treatment is due to the thyroid extract and to stimulation of the thyrotropic hormone of the anterior pituitary

gland is not known. It has been found empirically for the past twenty years that many patients with anterior pituitary deficiency, thyroepituitary obesity or adiposogenital dystrophy did much better when thyroid extract was given in conjunction with pituitary preparations. I now feel that this was due to stimulation of the thyrotropic element of the anterior pituitary gland. As to the question of treatment in mental retardation, I found that 66 per cent of the patients in the anterior pituitary deficiency group showed an improvement in the mental condition.

DR ROBERT L. SCHAEFER, Detroit. There are fallacies in every human growth increment curve. It was shown only to emphasize the fact that diagnosis in endocrine statural undergrowth should be made before sex maturity or the coincident thing, epiphyseal closure. It stands to reason that, if epiphyseal closure has been effected, no increase in statural height can be attained. If the growth hormone is then given and is of sufficient potency, the therapeutic result would be an abnormal one. Those osseous structures which derive their growth from the periosteum would be stimulated, in other words, a state resembling acromegaly might be produced. Glandular interrelationship, as Dr Hoskins has pointed out, is a broad subject. While considerable of definite clinical value is known, it cannot be discussed in brief. As to the psychologic aspect, such as mental retardation, none of these cases displayed any signs. They were all normal mentally, two bordering on precocity. That there is a definite relationship between the pituitary and thyroid, I believe. In study of the hypopituitary type of individual over a period of years I have very often seen that he is born with a normal mentality but that as the pituitary failure advances and the subthyroid factor becomes more pronounced mental retardation will intervene unless adequate treatment is given.

## DIAGNOSTIC FACTORS CONCERNING HERPES ZOSTER OTICUS

RALPH A. FENTON, M.D.  
PORTLAND, ORE.

Many otitic and intracranial conditions are simulated by the various manifestations of herpes zoster oticus. It may therefore not be without interest to review its etiology and pathogenesis up to the present, indebtedness to the pioneer studies of Ramsay Hunt,<sup>1</sup> Frank Dennis,<sup>2</sup> and W. H. Sears,<sup>3</sup> being kept in mind.

Knowledge of the nature and effects of the herpetic virus has lately been amplified by extensive immunologic study. It seems now pretty well agreed that the infectious agent is a filtrable virus, entering probably by the nose or nasopharynx, not by the skin.<sup>4</sup> This specific pathogenic agent becomes localized simultaneously in ectodermal structures—the skin and mucous membrane—and in the tissues of the sensory nervous system. It may travel from the cortex to the periphery or vice versa, vaccinating the neural structures along which it travels, which serve as its culture medium.

Theories of the pathogenesis of herpes zoster have entirely changed, it is no longer considered to be a ganglionitis alone but rather an ascending or descending

infective process due to a specific filtrable virus with definite serum reactions and antibody production.<sup>5</sup> In the affected nerves, lesions ranging from inflammation to hemorrhage and actual necrosis are found not only in ganglionic structures but also along the nerve sheaths to the periphery, and ascending even into the medullary nuclei, some report involvement of the cortical region concerned.<sup>6</sup> Histologically, the external manifestations observed are lesions of ectodermal structures due to selective action of the virus on the peripheral sensory neuron.<sup>7</sup>

Predisposing factors seem to include excessive heat or cold, exposure, severe physical trauma, nervous shock or exhaustion, and sudden loss of endocrine equilibrium. Granulomatous ailments such as tuberculosis and syphilis seem to increase the vulnerability of peripheral neurons to the specific toxin of this disease.<sup>8</sup> It has been suggested that chronic septic states caused by long-standing colonic stasis, cholecystitis, dental apicitis or nasal sinusitis may similarly facilitate meningeal invasion by the herpetic virus.

Certain recent work in immunity raises the question of the transportation of this virus by connective tissue phagocytes (histiocytes), themselves not injured by its effects, along meningeal lymph channels or tissue spaces, but this has not yet been demonstrated.

Much discussion has taken place concerning the alleged kinship of the virus of chickenpox with that of herpes zoster, the latter being predominantly a disease of mature individuals.<sup>9</sup> Some consider herpes zoster to be due to the reactivation of a latent chickenpox virus by added toxic or infective stimuli. But zoster is not contact transmissible, nor does previous varicella immunize against herpetic disease. While Goodpasture and Teague<sup>10</sup> in 1923 decided that zoster was merely a virulent form of simple herpes, Levaditi and most of the recent investigators, including Olitsky of the Rockefeller Institute, are convinced that herpes zoster is due to a specific and distinct virus.<sup>11</sup> So far, it has not been inoculable into animals or man, while herpes simplex may be readily transferred by special methods.<sup>12</sup>

The skin lesion of herpes zoster, a vesicle, resembles that of smallpox but contains more exudate, it is due to intercellular edema with local necrosis and the appearance of Unna's "balloon" cells, large, swollen and multinuclear. Late skin changes include a thickened stratum corneum and proliferation of pigment cells, with depressed fibrotic zones when secondary infection has occurred.<sup>13</sup>

The peripheral nerves at first show lymphocytic infiltration and small hemorrhages in their interfibrillary spaces. So-called oxyphilic inclusions—"herpetic bodies"—are later found along the nerve sheaths, with

myelin degeneration, followed by regenerative changes on recovery.<sup>13</sup>

The sensory ganglions show both interstitial and periganglionic round cell infiltration, occasionally with necrosis arising from severe congestion. Later, chromatolysis with atrophy, vacuolization and disappearance of ganglion cells may occur, followed by fibrotic capsular proliferation. The axon cylinders may become swollen to ten or fifteen times their normal size. Still later, fibrous changes occur, with histiocytes and fibroblasts carrying on the work of repair. Similar changes are found in the nerve roots and meningeal coverings involved. Postmortem reports on a few cases complicated by facial palsy disclose wallerian degeneration, especially below the geniculate ganglion, and, possibly owing to a retrograde process, involvement of the seventh nucleus has been found.<sup>14</sup>

Symptoms and signs, in addition to vesicle formation (which may be limited to the posterior wall of the external auditory meatus or to one or two small lesions on the concha or mastoid), include pain, which may rarely disappear on drying of the vesicles but usually lasts weeks, occasionally months, an enlarged preauricular lymph node (occasionally mastoid, cervical or parotid), loss of local tactile sensibility, and sometimes vesicles on the anterior two thirds of the tongue, the anterior pillar or soft palate of the same side. Facial paralysis may supervene four or five days after, rarely coincidental with or preceding the eruption. Extensiveness or depth of vesiculation has nothing to do with the advent of paralysis. Pain accompanying facial palsy should always suggest herpes zoster.

Vestibular and auditory symptoms—moderate vertigo, slight deafness or buzzing noises—may precede the eruption by several days or appear simultaneously. Transitory in character, the dizziness is usually more annoying than the hearing disturbances.

Various combined nerve involvements have been reported both facial and auditory nerves, one branch of the fifth, the first cervical, and, rarely, one intercostal nerve along with various cranial divisions.<sup>15</sup>

#### REPORT OF CASES

Classification of the symptoms may perhaps be facilitated by brief reports of three typical cases recently observed.

CASE 1—A woman, aged 36, somewhat neurotic, had noticed for two days a slight tingling and itching of the inner surface of the concha and posterior rim of the external meatus. Slight serous discharge had followed rubbing of this area with cotton. She complained of a slight buzzing in the ear but no loss of hearing. Seven herpetic vesicles, either drying or with their tops rubbed off, were found at the junction of the concha and the external canal, two being just inside. The posterior half of the tympanic membrane was slightly pinkish. These lesions healed in two days with dithymoldiodide dusting powder.

CASE 2—In a robust man, aged 42, accustomed to outdoor work, the condition came on forty-eight hours after severe exposure of his hatless scalp for an entire day to the summer sun. The next day he complained of some headache but kept on with his unusually heavy work. That night his headache became so violent that he became irrational, with a temperature of 101.6 F, requiring restraint and hypnotics. Before the

latter could take effect, however, thorough cocainization of both sphenopalatine areas of the nose was done, because of the retro-auricular localization of the pain. This gave him immediate relief, and he became quiet and tractable. Hearing was but slightly affected, although both tympanic membranes were pink. There was marked dizziness, however, with spontaneous rotatory nystagmus on abduction to either side, this was almost gone in forty-eight hours more. There was marked venous engorgement of both optic disks at first, disappearing after the first day. No herpetic vesicles were found on the anterior surface of either pinna or within the meatus, however, both ears showed a crop of from twenty-five to thirty vesicles over the back of each pinna, with three on the skin over the left mastoid. Additional herpetic vesicles were noted on the right ala nasi, about both angles of the mouth, and on the right side of the soft palate. Hearing loss or facial asymmetry was not noted at any time.

After rapid saline purgation and the local use of alcohol-acetone solution of metaphen 1 200, with daily shrinkage of the sphenopalatine regions, the vesicles were gone in three days, and the patient went to work after eight days.

CASE 3—A woman, aged 45, referred by the medical and neurologic services in Multnomah Hospital for diagnosis, had been having a temperature of from 101 to 102 F for several days, with swelling and tenderness back of one ear suggesting erysipelas. Roentgenograms showed slight blurring without loss of trabecular sharpness. The external meatus was almost swollen shut and the tympanic membrane was deep red, but hearing was almost normal. A constant deep boring pain behind the ear had suggested the idea of a fulminant mastoid, there was a history of otitis media in early childhood. After five days the face became paralyzed, remaining flaccid nearly nine weeks thereafter. Synchronous taste disturbances were noted on the back part of the tongue on the same side. But following the palsy, dizziness was the chief complaint for several days, there was also slight and transitory hearing loss, with the Weber test referred to the opposite side.

Several drying vesicles were found on the mastoid skin, behind the swollen concha and along the posterior meatal wall. An intercurrent bronchopneumonia kept her temperature high for ten days. Making the diagnosis of herpes zoster oticus, my service refused either a myringotomy or a mastoid operation. Under use of alcohol-acetone metaphen the skin swelling was gone in two weeks. Pain in the mastoid region running to the top of the head remained a most disagreeable feature for almost twelve weeks.

Here is seen, first, the very mild and superficial affair simulating an eczema, secondly, the furiously severe type with meningeal symptoms, but little local annoyance in spite of very extensive skin lesions in several nerve areas, and, thirdly, dermal manifestations resembling erysipelas followed by facial palsy, with severe mastoid pain and without meningeal symptoms.

I have not seen any of the cochlear-vestibular symptom complexes, often very severe and showing 11 per cent facial paralysis in the French series last reported.<sup>16</sup> These may show either much deafness, much dizziness, or both.

Based on these four clinical forms, differential diagnosis may be considered from several angles. First, the diffuse and painful swelling over the mastoid, concha and posterior wall of the external meatus, prior to the appearance of herpetic vesicles or after such vesicles have dried up or coalesced into open ulcers, must be distinguished carefully from other causes of similarly painful edema. Obviously, periosteal swelling from mastoiditis will show deep tenderness on pressure of the antrum and blurring of cell outlines in the roentgenogram. Edema from furunculosis, aside from the classic pain on traction of the pinna, will show definite tender swellings within the canal, often anteriorly. Eczema or pyoderma about the canal lacks the severe neuralgic pain of herpes zoster. Erysipelas

<sup>15</sup> Browne. *Rebattu Mounier Kuhn Dechaume Bonnet and Colrat.* 4 Pardee.

shows a higher temperature, from 101 to 104, rather than from 99 to 101 in herpes zoster. Its raised, subdermal lymphatic invasion, brawny and reddened, will speedily clear up the diagnosis. But occasionally bullae form over the mastoid or pinna in erysipelas, usually irregular in form, not small rounded vesicles as in herpes zoster. Such eruptions may cause much confusion for a day or two.

Within the auditory meatus, acute eczema or pyodermic lesions arising from fissures may suggest eroded herpetic areas, but the fissure concerned will always be found, after removal of crusts, and no vesicles will be noted on the back of the pinna or mastoid. Lesions from herpes zoster cannot be confused with the red, crusted, intertriginous fissuring of eczema between the pinna and its attachment to the mastoid skin.

Fungoid invasion of the meatal epithelium does not attack the pinna, although eczema, fissuring and erythema caused by the acrid discharge of various ringworm and mold invasions may be momentarily confusing. Musty smelling soft gray masses in trichophytosis or dry and powdery crusts in aspergillosis, filling the lumen of the canal, without vesicular lesions or neuralgic pain, remove any doubt. Myringitis bullosa lacks the characteristic pain of zoster and shows no skin vesicles.<sup>16</sup>

In the absence of middle ear infection, facial paralysis accompanied by severe pain suggests certain remote possibilities. For example, after an accident in which basal fracture or tearing of meningeal vessels has led to hemorrhage about the internal auditory meatus or within the tympanic cavity, facial paralysis may show up hours or even days after the injury, and tension of the dura across the gasserian fossa may produce associated pain of severe degree. But this history of direct violence is almost unheard of in herpes zoster oticus. Exposure, when it is a factor, is usually to sun and wind, during a long motor ride or work outdoors, occasionally this occurs when the patient goes out into sharp weather after some debilitating illness, notably syphilis. The action of chilling of the mucosal surfaces in facilitating invasion through the nose by lowered resistance to the herpetic virus deserves experimental study. Lesions of the seventh nerve from tumors or cysts at the cerebellopontile angle present definite vestibular and ocular symptoms which are constant, slowly increasing and usually painless. Vestibular and cochlear phenomena in herpes zoster are transitory, show up early and are always coupled with pain whether facial palsy is present or not.

When there is doubt concerning the presence of herpetic lesions with facial palsy, it is interesting to recall that Aitken and Brain, following Netter's preliminary studies, have recently discovered a specific antibody in the blood of eighty out of eighty-two convalescent zoster patients.<sup>17</sup> Eight cases of facial paralysis with a history of eruption gave a positive complement fixation to this antibody, while of twenty-two palsies without eruption eighteen gave negative complement reactions, two partially positive, and two positive. From the standpoint of prognosis, since zoster paralyzes due to swelling about the geniculate ganglion are almost all transitory, this test seems to afford a valuable aid

Disturbance of other nerves than the seventh and eighth is uncommon. Nevertheless in those cases of herpes zoster associated with marked meningeal symptoms (the so-called encephalitic type), numerous other nerves of either side may be involved, notably the maxillary and mandibular divisions of the fifth. Thus palatal, nasal and labial herpes may accompany herpes zoster oticus, usually at the start, activated apparently by the same dose of virus in adjacent regions of the medulla. Disturbance of taste without facial palsy and, very rarely, slight involvement of the forehead from the ophthalmic fifth<sup>18</sup> have been reported but are of brief duration. Certain observers bring up the question whether synchronous invasion of motor nerves along with that of the sensory pathways may not occur, but the usual delay of several days in motor symptoms speaks for the generally accepted opinion that such involvement is due to secondary pressure on and infiltration of motor nerves passing through the bony canals, foramina or dural envelops concerned.<sup>19</sup>

Symptoms referred to the brain and meninges—violent, boring or band-like headaches, often with transitory rise in temperature and mental irritability and confusion—may suggest analogies to other diseases of these structures, whenever the early external manifestations of herpes zoster have not been noted. Such conditions include intracranial hemorrhage in hypertension or thrombosis, when blood pressure is low, the prodromal stages of encephalitis or of epidemic cerebrospinal meningitis and invasion by or extension of intracranial neoplasms or abscesses. Urinalysis, blood pressure readings and electrocardiograms may be needed in the first class, lumbar puncture, disclosing pressure, high cell count or turbid fluid, may relieve the acute intracranial pressure pain of meningitis but will not allay the intrinsic neuralgia from swelling of the radicular ganglionic structures in herpes zoster. Similar transitory relief from spinal or ventricular puncture may occur in cases of tumor or abscess in which encephalograms will disclose characteristic deformation of the ventricle nearest the lesion. Also, in abscess the causatory chronic otitis or frontal sinusitis may readily be located. However, none of these difficult diagnostic procedures will be necessary if the clinician is on the lookout early and often for local signs of herpes zoster—erythema, edema, vesiculation, and superficial pain limited to the sensory distribution of the seventh nerve.<sup>20</sup>

It should be recalled that herpes material inoculated into the meninges of experimental animals causes encephalitic changes but no herpetic manifestations. Ohtsky and his co-workers on filtrable viruses have repeatedly demonstrated that the neurotropic action of encephalitis virus can be changed into a dermatotropic attack by subdermal pad inoculation in animals. Stomatitis virus can thus be made neurotropic, and it will be found to pass readily from the nasal mucosa of mice to the meninges and brain.<sup>21b</sup>

It seems probable that increased susceptibility in syphilitic patients to herpes zoster may be due at least in part to blocking of the normal histiocytic defensive structures of the brain, nerves and meninges by the previous spirochetal infestation, with subsequent fibrotic changes. Similarly impaired resistance to the herpetic

virus is noted in leukemic, diabetic, arteriosclerotic and senile individuals and in those long subject to treatment with arsenic and bismuth compounds. Irritation of the skin of guinea-pigs by coal tar was a necessary preliminary to successful production of herpetic lesions by human material in the classic work of Teague and Goodpasture, they also demonstrated encephalitis and typical herpetic inclusion bodies in the brains of inoculated rabbits.

Severe pain in the facial sensory distribution, relayed at the geniculate ganglion from the great superficial petrosal and vidian nerves, may be caused by sinusitis affecting the sphenoid or posterior ethmoid, and rarely by various irritative or malignant lesions of the nasopharynx, larynx and basilar process.<sup>21</sup> Here, again, close observation will disclose no skin lesions and rarely any enlarged or painful glands, unless very severe sinusitis or a metastatic malignant condition is present. Neuralgias due to dental caries, use of arsenicals in root canals, impacted third molars, undescended cuspids, cysts, osseous tumors of the jaw and like conditions are similarly easy to segregate, if necessary by roentgenographic evidence, from the pains of herpes zoster. Obviously, interference with speech and other characteristic local conditions will rule out otalgias caused by ulcers, granulomas or neoplasms of the tonsil, epiglottis, larynx and lateral pharyngeal wall.

The management of herpes zoster oticus is symptomatic. So far, since the virus has not yet been isolated, no specific treatment is possible. The serum of cured cases has been stated to attenuate or shorten the duration of postherpetic pain. "Shock" treatment has been advocated—foreign protein injection—as well as auto-hemotherapy, from 5 to 10 cc of the patient's own blood being used intramuscularly.<sup>4b</sup> Recumbency aggravates the pain of herpes zoster, such individuals are better off out of bed unless they have a fever or other complications. Ultraviolet irradiation is found very helpful in shortening the duration of the pain.

Locally, dry open treatment with nonirritating powders or mild, quick-drying antiseptics will obviate secondary infection of the vesicles and prevent scarring.

Cocainization of the sphenopalatine region is often very helpful in cutting down pain and vertigo at the period of geniculate ganglion swelling. The middle ear should be left severely alone unless an intercurrent otitis media requires surgical measures, a very rare complication.

After the congestive stage has passed, diathermy may be tried if residual pain is excessive. Alcohol injection of the sphenopalatine ganglion and pericarotid sympathectomy have been tried, but confirmation of their good effects is conspicuously lacking.

Since the facial paralysis usually clears up within a few weeks, faradic treatment or operative procedures for decompression of the seventh nerve should not be considered until the paralysis has lasted, unchanged, for at least two or three months. Every case of Bell's palsy should be closely examined for traces of herpetic vesicles, and in case of doubt a complement fixation test against a known herpes zoster virus should be made.

It is not unlikely that many cases of herpes zoster oticus pass unrecognized, because of their close resemblance to other diseases of this region, and it is

suggested that recognized cases receive careful immunologic study, particularly in those institutions possessing apes and monkeys for experimentation. Only through such laborious and long-continued studies of the filtrable viruses will it be possible to attack this disabling and painful disease effectively.

1020 Southwest Taylor Street

#### ABSTRACT OF DISCUSSION

DR HARRIS P MOSHER, Boston. It has been a long time since I have had my imagination stimulated so much. This is a dramatic disease. The story fortunately, always ends happily. There is probably no other disease in otolaryngology which simulates so many other diseases. Its mimicry is shown by the fact that in one case meningitis has to be ruled out, in another mastoiditis, and in another even fracture of the base of the skull. It has been proved that it is not the ganglion alone that is involved but all nervous tissue. It can be either an ascending or a descending neuritis. There is, however, a selective action on the peripheral sensory nerves. Experimentation has shown that the stomatic virus can be made selective for nerve tissue in mice and that it will pass from the nasal mucosa to the meninges and the brain. The most important practical point is that in patients suffering from herpes there is a specific antibody in the blood. Therefore, in case of paralysis of the facial nerve of doubtful origin not only a careful examination for vesicles but also a complement fixation test against a known herpetic virus should be made. The innocence of the outcome of herpes zoster oticus, in spite of its worrying manifestations, seems to me to have a parallel in certain ear cases in which the Gradenigo syndrome is present. Some of these cases clear up without operation, some with a simple mastoid operation, by no means all require drainage of the petrous tip. In other words, the mild cases are accompanied by an innocent toxemia of the sixth nerve and of the gasserian ganglion. I have the feeling, in the light of a few recent autopsies, that the gasserian ganglion will bear close watching. I am wondering whether more often than is supposed it does not pick up infection from the nasal sinuses or pharynx. In other words, may it not be the first intracranial structure to be infected and the starting point for infection of the dura or the deeper tissues?

DR GORDON F HARNNESS, Davenport Iowa. Dr Fenton has reviewed a condition that is rare as a clinical entity, self limited, with unproved etiology, and without any specific therapy. Its differential diagnosis demands the exclusion of a fulminating type of mastoiditis. This is not so difficult, but the rarity of herpes zoster oticus is responsible for its symptomatology not always being kept in mind and has resulted in mastoid operations being performed when the significant symptoms were improperly interpreted. With the eruption and its characteristic distribution, diagnostic errors are largely eliminated. While the facial paralysis generally follows and less commonly is coincidental, it has been reported as preceding the vesicular stage. The deafness is always predominantly that of nerve involvement. The disturbance of taste and surface eruptions on the tongue, in the area of chorda tympani distribution, are significant. Careful observation of the membrana tympani, and the absence of any perforation, are important. Finally, the roentgenogram of the mastoid should add comfort to a course of watchful waiting. It is particularly confusing to speak of herpes zoster as a posterior polyomyelitis. Particularly in the seventh nerve does one have the close proximity of sensory and motor pathways enclosed in a bony canal, so that one can readily conceive of the ease with which inflammatory reactions are transmitted from sensory to motor fibers. The cells of the geniculate, gasserian, ninth, tenth and posterior spinal ganglia are unipolar in type. Histologically they are of a sensory type. The pars intermedia or nerve of Wrisberg constitutes the posterior root of the geniculate ganglion. Parasympathetic fibers from a nidus of cells in the medulla in close proximity to the facial nucleus, leave as constituent elements of the pars intermedia, the nerve of Wrisberg. They constitute preganglionic fibers and by way of the

<sup>21</sup> Somogyi.<sup>14</sup> Sluder Greenfield. *Nasal Neurology Headaches and Eye Disorders*. St. Louis C. V. Mosby Company 1927 (bibliography).  
Fenton R. A. and Larsell, Olof. *The Mechanism of Pain Transmission in Certain Types of Otalgia*. Tr. Int. Cong. Oto-Rhino-Lar. Copenhagen Jensen 1928 p. 562.

chorda tympani and lingual nerves go to the submaxillary and sublingual glands and, by the great superficial petrosal, to Meckel's ganglion. The relief afforded by cocainization of the sphenoid cavity would tend to support the contention of Sluder that the nerve of the pterygoid canal carries afferent impulses. I cannot discuss this paper from the standpoint of the sympathetics and the parasympathetics because I have been unable to find any data that would accord these nerve subdivisions a place as etiologic factors. There are probably variants of this disease involving the fifth, ninth, tenth and cervical nerves. They are also more frequently not so recognized. In this disease, anatomic structures and contiguity of tissues endow it with a striking clinical picture. When a study of the variant types is followed as closely, physicians may be in a better position to discuss etiologic factors.

DR HARRIS H. VAIL, Cincinnati. Herpes zoster is complicated by so many factors, such as trauma, syphilis, metastatic malignant conditions of the spine, tuberculosis and fracture of the spine, surgical operations, arsenic and bismuth poisonings, acute and chronic progressive central nervous disease and senility, that Dr Fenton's presentation is timely. While I can find no fault with the author for citing the comprehensive review of Rebatu and his associates as authority for the statement that the virus of the herpes may travel from cortex to periphery or vice versa, vaccinating the neural structures along which it travels, which serve as its culture medium, my reaction is to challenge that statement. Marinesco states that the process in herpes zoster is an ascending and descending one. My interpretation of Marinesco's article is that his case was not herpes zoster, as there were neurologic evidences of thalamic disease, and postmortem examination four years after a vesicular eruption on the thigh showed active infiltration of the involved ganglions with round and plasma cells. Plasma cell infiltration is not found in true zoster. Marinesco felt that the virus of herpes zoster entered through the skin. Dr Fenton states that the virus enters probably by the nose and nasopharynx and gives as an authority F. E. Browne of Australia. As three of Browne's four patients were orchardists, I presume that arsenic insecticides were used. Arsenic poisoning was not considered nor in my opinion was sufficient evidence given to prove that the nasopharyngitis was the factor. The second case reported by Dr Fenton is interesting but hardly one, I think, of herpes zoster. Cocaine injected into the sphenoid sinus might reach the vidian nerve better than that applied to the sphenopalatine area. Paracentesis seems to be under a tabu, and in reporting his third case Dr Fenton said "Making the diagnosis of herpes zoster oticus, my service refused either a myringotomy or a mastoid operation." The advisability of paracentesis in herpes zoster oticus with a normal tympanic membrane might be argued, but there should be no argument in a case presenting a deep red tympanic membrane. Why should this simple procedure be contraindicated when it will provide a drainage outlet? Can an inflammation localized to only a small portion of the middle ear be ruled out with certainty? In all other forms of acute otitis media, paracentesis is indicated. I wish to ask Dr Fenton why it was contraindicated in his case.

DR RALPH A. FENTON, Portland, Ore. I am grateful for these discussions. In case 1, the inflammation started posteriorly and worked forward. The inflammation did not proceed from the middle ear, there was no bulging, and I refused to do a paracentesis. The patient's hearing was normal, she had no middle ear disease. If paracentesis had been done, the middle ear would speedily have been infected from the open ulcers in the back wall of the canal. The second case was definitely one of herpes zoster but was bilateral, which is rather unusual, although I have found several reports of such things in the literature. There is no question about the case having run the regular course, because these vesicles dried up quickly behind the ears and on the face. Respecting the question of relief of the pain in this man's case by shrinking the sphenoid regions, it should be realized that he was out of his head, raging about the house, only because he was a good friend of mine could I get him to sit down long enough to get probes up past the middle turbinates. Shortly thereafter he said that he felt all right and went back to bed.

## GASOLINE AND KEROSENE POISONING IN CHILDREN

JOHN A. NUNN, M.D.

AND

FRANK M. MARTIN, M.D.

SAN ANTONIO, TEXAS

This article comprises a summary of the clinical and laboratory examinations in seven cases of gasoline poisoning and sixty-five cases of kerosene poisoning in children admitted to the Robert B. Green Memorial Hospital between October 1931 and July 1933. The ages ranged from 10 months to 4 years. A considerable number of children have been brought to the emergency room of the hospital with a history of having taken one or the other of these petroleum products. Only those showing signs of acute poisoning, however, were admitted to the hospital. Those showing very little evidence of acute poisoning were allowed to return to their homes after treatment consisting of gastric lavage and a laxative. The essentials of several of the cases are herewith reported.

### REPORT OF CASES

CASE 1—A boy aged 14 months, Mexican, was admitted in a stuporous condition. He had swallowed a "small amount" of gasoline about thirty minutes before admission. Respiration was labored (40 per minute), the pulse was 140 per minute and the temperature 98.6 F. Examination of chest revealed many medium-sized and fine moist rales throughout both lungs. He was treated by gastric lavage, caffeine sodiobenzoate and atropine hypodermically. Death occurred one hour after admission. Autopsy revealed edema of the lungs, the alveoli being filled with fibrin and serous exudate, fatty degeneration of the liver and dilatation of the stomach. The stomach contents had a strong odor of gasoline.

CASE 2—A boy aged 17 months, white, drank about an ounce of kerosene a few minutes before admission. He was acutely ill and stuporous. The pulse was 140, the temperature was normal, and the respiration rate was 32. Examination of the chest revealed numerous large moist rales throughout both lungs. Treatment consisted of gastric lavage, atropine and caffeine sodiobenzoate hyperdermically and the administration of a saturated solution of magnesium sulphate through the stomach tube after the lavage. Two hours after admission, the temperature was 106.5 F. One hour later the temperature was unchanged, the respiration rate was 56 and the pulse was too rapid to count, at which time the patient died.

CASE 3—A boy, aged 2 years, a Mexican drank 2 ounces (60 cc) of kerosene thirty minutes before admission. He was stuporous and the abdomen was greatly distended. The lungs were clear, the temperature was 100, the pulse was 128 and the respiration rate was 50. During gastric lavage, the child aspirated some of the contents of the stomach, after which moist rales rapidly developed in both lungs. He became restless and twelve hours after admission convulsions developed, which persisted until death two hours later.

CASE 4—A white boy, aged 11 months, drank an unknown quantity of gasoline thirty minutes before admission. At the time of admission he was cyanotic and comatose. The pupils were dilated and the eyes were rolled upward. The temperature was 97.8, the pulse 150 and the respiration rate 40. He had been made to vomit before he was brought to the hospital. There were many moist rales throughout both lungs. In spite of routine treatment such as previously outlined, the patient showed no improvement and died one hour after admission.

CASE 5—A boy aged 1 year, drank an unknown quantity of kerosene just before admission. He was apparently not very sick. The temperature was 101 and the pulse and respiration rates were normal. The results of examination were essentially negative. Urinalysis was negative. The white blood count was 11,000 with polymorphonuclears 70 per cent.

and lymphocytes 30 per cent. Two days after admission, coryza developed and moist râles appeared in both lungs, caused, we believe, by the development of a respiratory infection subsequent to taking the gasoline rather than to pulmonary irritation from gasoline. The temperature remained around 101 for four days and then fell to normal. The lungs cleared and the patient was discharged on the fifth day in good condition. The treatment consisted of gastric lavage at the time of admission.

**CASE 6**—A girl, aged 15 months, a Mexican, drank a fourth of a cup of kerosene four and a half hours previous to admission. The mother immediately gave the child castor oil. There was no history of cyanosis or other evidence of respiratory embarrassment. Medium-sized moist râles were heard in the apex of the left lung, and the abdomen was distended. The temperature was 101, the pulse 110, and the respiration rate 30 on admission. Gastric lavage was omitted in this case. Atropine sulphate was given by mouth. The white blood count was 12,000, with polymorphonuclears 72 per cent, and lymphocytes 28 per cent. Urinalysis was negative. The temperature dropped to normal the next day and by two days after admission the signs in the lungs had disappeared. The patient went home in good condition on the third day.

**CASE 7**—A girl, aged 16 months, a Mexican, was admitted to the hospital three hours after drinking an unknown amount of kerosene. She had vomited some of the kerosene immediately after taking it. On admission she was comatose and cyanotic, and the respiration was labored. The temperature was 101 on admission and rose to 104 within two hours, at which height it remained for twelve hours. The examination on admission showed moist râles throughout both lungs. The white blood count was 9,650, with polymorphonuclears 80 per cent and lymphocytes 20 per cent. The urine showed a trace of albumin. When the temperature was at its height, the rate of respiration varied from 40 to 56 per minute. Sixteen hours later it dropped to 30 and the temperature became normal about the same time. The routine treatment of gastric lavage and atropine sulphate hypodermically was employed. The lungs cleared by the third day and the patient went home in good condition.

**CASE 8**—A girl, aged 2 years, a Mexican entered the hospital one and one-half hours after drinking half a glass of gasoline, according to the history. The mother gave the child 1 ounce (30 cc) of olive oil immediately. When seen in the emergency room, she was semicomatose and cyanotic, and appeared to be critically ill. The respiration rate was 50, the pulse 120 and the temperature 99. Many fine moist râles were heard throughout both lungs. The patient was given gastric lavage, caffeine sodiobenzoate and atropine, and external heat was applied. A mixture of carbon dioxide 5 per cent and oxygen 95 per cent was administered by nasal tube together with artificial respiration for eleven hours. During this critical period the temperature rose to 106. She became more cyanotic, and coma became more pronounced. After this the temperature began to decline and twelve hours later it was normal and the child was conscious. Twenty hours after admission she was greatly improved and at the end of forty eight hours the lungs were clear and the patient was discharged in good condition.

#### COMMENT

The total mortality of these seventy-two cases was 11 per cent. Among the kerosene poisoning cases it was 92 per cent, while in the small series of gasoline cases (seven) it was 28 per cent. In the fatal cases the children lived from two to eighteen hours after the ingestion and the aspiration of these substances. All the children who died showed definite clinical evidence of pathologic changes of the lung, namely, many moist râles in both lungs, rapid, shallow respirations and cyanosis. Convulsions occurred in two of the fatal cases and in two of the nonfatal cases. Of the nonfatal cases, twenty-two, about 32 per cent showed some evidence of pneumonitis, as evidenced by moist râles in the lungs. From these observations it would appear that about one third of the patients who had swallowed a

large enough quantity of the substance to become sufficiently ill to require hospitalization had also aspirated some of the fluid.

The temperature in this series ranged from 97 in the fatal cases to 103 in cases of moderate severity, and it reached 106 in a few of the severe cases. The pulse rate varied from 110 to 150 in the moderately severe cases and was so rapid and weak in some of the fatal cases that it could not be counted. The respiration rates were very rapid, ranging from 50 to 80 per minute in those cases showing evidence of pneumonitis.

The white blood counts varied from normal to 21,000, with polymorphonuclear percentages of 65 to 80. The blood pictures were otherwise normal. The red blood cells and hemoglobin were within normal limits. The urinalyses showed an acid reaction with an occasional 1 plus albumin (ten out of our seventy-two cases). Anuria or painful urination was not observed in any case.

The toxicity produced by the ingestion of coal oil or gasoline need not cause the great concern that aspiration or inhalation of these hydrocarbons causes. Our patients who only drank the fluid showed symptoms of intoxication such as restlessness, incoordination, cyanosis, vomiting and loose stools, with no signs of pneumonitis. These symptoms were followed by a period of depression, which persisted only a few hours, after which the patients were apparently out of danger. They usually responded well to stimulation, emptying of the stomach and catharsis.

The patients who aspirated, as well as ingested, one of these petroleum products presented a much graver clinical picture, owing to the rapid development of pneumonitis, which was evidenced by cough and many moist râles throughout both lungs. In all the fatal cases in our series, there were physical signs of pneumonitis. It is believed that the pneumonitis was produced by the irritating properties of these substances, while the marked evidence of involvement of the central nervous system (cyanosis, rapid and feeble respiration, rapid and weak pulse, restlessness, coma and convulsions) is due to the rapid and overwhelming absorption of the volatile fractions by the pulmonary circulation, this absorption being facilitated by the thin permeable alveolar wall. We feel that the toxic fractions of these oils reach the vital centers of the central nervous system much more rapidly and in larger amounts when absorption takes place in the lungs. Absorption of these substances from the gastro-intestinal tract alone is much slower. There is also the possibility of some detoxification being accomplished by the liver. We feel that the symptoms of gasoline and kerosene poisoning are produced by the toxic action of these substances on the central nervous system, principally the respiratory center motor areas and the vagus center.

There is apparently no loss of oxygen carrying capacity of the blood. Waring<sup>1</sup> in his blood studies in cases of kerosene poisoning was unable to find methemoglobin in the blood. He showed by his experiments on dogs that as much as 100 cc of kerosene administered by stomach tube produced only slight temporary ill effects, while as small a quantity as 10 cc injected into the trachea resulted in death in from six to eight hours.

The prognosis may be said to be in direct ratio to the amount of the hydrocarbon that enters the lungs,

<sup>1</sup> Waring, J. I. Pneumonia in Kerosene Poisoning. *Am J M Sc* 185: 325 (March) 1933.

and it has been our observation that if the patient survives several hours he recovers completely. There are practically no complications or sequelae in this type of poisoning. The irritating effects in the lungs and the gastro-intestinal tract disappear completely in from forty-eight to seventy-two hours.

#### TREATMENT

There appears to be no specific antidote for gasoline or kerosene poisoning. Treatment consists of removing as much of the offending agent as possible by gastric lavage or emesis and laxatives. During gastric lavage there is much retching, struggling and breath catching, which seem to favor aspiration of stomach contents into the lungs. It is our impression that there is less likelihood of aspiration of the fluid when emesis is produced by the oral administration of syrup of ipecac than when gastric lavage is employed. In our more recent cases when cyanosis and other signs of respiratory embarrassment are present, we believe that the use of oxygen (95 per cent) and carbon dioxide (5 per cent) has been of considerable benefit. We therefore recommend the administration of oxygen and carbon dioxide in all cases that show such signs. It is employed for its stimulating action on the respiratory center rather than to increase the oxygen-carrying power of the blood. We have also given atropine sulphate and caffeine sodiobenzoate hypodermically for their stimulating effects.

### DILAUDID AND MORPHINE EFFECTS ON BASAL METABOLISM AND OTHER BODY FUNCTIONS

NORMAN A. DAVID, M.D.

MORGANTOWN, W. VA.

Dilaudid (dihydromorphinone hydrochloride), a new morphine derivative,<sup>1</sup> was first introduced into this country from Germany in 1932 by Alvarez.<sup>2</sup> Eddy<sup>3</sup> has reviewed the foreign literature and reported preliminary experimental studies of the toxicity and action of this drug in animals. Paine, Carlson and Wangenstein<sup>4</sup> used dilaudid in the treatment of nineteen patients and considered it effective in controlling pain but not superior to morphine in decreasing the incidence of postoperative distention, nausea and vomiting. Diehl,<sup>5</sup> in his study on the medicinal treatment of the common cold, found a combination of dilaudid and papaverine as efficient as the codeine-papaverine preparation which he recommends but more likely to produce undesirable side-effects.

The chief advantages claimed for dilaudid over morphine are that its repeated use has less tendency to produce habit formation and that there are fewer unfavorable side-effects, such as nausea, constipation

and euphoria.<sup>6</sup> Eddy,<sup>3</sup> however, especially stresses that addiction to dilaudid as well as the occasional appearance of toxic symptoms has been reported by some German authors. When used in small therapeutic doses, dilaudid is said to allay pain and cough effectively with little tendency toward narcosis or depression of the respiratory center. Because the compound is more toxic than morphine the recommended dose is about one-fifth that for morphine,  $\frac{1}{32}$  grain (2 mg.) of dilaudid corresponding to  $\frac{1}{6}$  grain (10 mg.) of morphine sulphate.

Information of practical value may be obtained by a comparative study of the effects of dilaudid and morphine on the basal metabolism, tactile discrimination and other body functions in normal adults. Previous workers<sup>7</sup> have shown that morphine and codeine within therapeutic ranges tend to lower the basal metabolic rate in proportion to the dose given. Correlation of this effect with the reduction of tactile discrimination offers a method of estimating the intensity of the action of central nervous system depressants, particularly those which produce both analgesia and narcosis.<sup>8</sup> Further significant data are to be obtained in carrying out a study of this nature by observing the changes in the various body functions and recording the incidence of unfavorable side-actions.

#### METHODS

The drugs were administered subcutaneously in proportion to body weight to normal young adults, mostly male, aged from 18 to 31 years. One group of ten subjects served as controls and received a placebo of a grain of lactose in 1 cc. of water.

The determinations of oxygen consumption were made by the closed method with the Sanborn "graphic" apparatus, and the Sanborn averages were used for estimating the basal metabolic rate. All initial determinations were made after a fast lasting fifteen hours and after a period of rest in bed lasting thirty minutes. Following the administration of the drug, metabolism tests were taken at intervals of twenty, sixty, ninety and one hundred and twenty minutes. The pulse rate, blood pressure, temperature and tactile discrimination were also observed and the subjective symptoms were recorded between the metabolism tests. The respiratory rate was obtained directly from the metabolism chart. Tactile discrimination was studied by noting the subjects' ability to distinguish between one or two points of pins on the volar surface of the wrist, care being taken that the same restricted area was tested each time. Two days after the test, the subjects returned to report on the occurrence of unfavorable after-effects.

Table 1 shows the doses of the drugs employed, the number of subjects treated in each group and the average maximum changes from normal during the two hours after the drug was given. The accompanying chart shows for each dose and drug used the changes in the metabolic rate over the two hour period of the test. The incidence of undesirable side-effects is shown in table 2. In this table data have been included on a number of additional subjects who received drugs but

From the Department of Pharmacology, University of West Virginia School of Medicine. Appreciation is acknowledged of the assistance rendered by Kenneth A. Rothery, M.D., Rupert W. Powell, A.B. and D. Gerald Nyhan, A.B. in many of these experiments.

whose cases have not been reported either because the initial metabolic rates were not within normal ranges or because they did not take the metabolism tests. In the latter group are a number of medical students who received subcutaneous doses of these drugs in the laboratory in order to study the effects of opium derivatives in man.

A control group of ten subjects who were given placebos was tested in the same manner as those taking drugs. This provided information with respect to the influence of various environmental factors on the individual when subjected to a number of metabolism tests and observations over a period of several hours. While precautions were taken to secure complete relaxation and the subjects, believing they had received a drug, attempted to sleep between tests, it is interesting to note that there was a gradual rise in their metabolic rates. This may be attributed to the subject's increasing restlessness due to hunger, the discomfort from prolonged lying in bed, the psychic fear of the hypodermic injection and the annoyance of constant subjection to the tests. The other body functions showed little variation from the normal, the temperature and respiratory rate tending to increase slightly and the pulse rate and pulse pressure tending to fall. In three subjects tactile discrimination decreased in sensitivity, while in the majority an increase in acuity was noted with successive trials.

#### DRUG EFFECT

Dilaudid seemed to act more rapidly than morphine. With either drug within a period of five to fifteen minutes after the injection the subject usually experienced a sense of intense hunger and noted considerable borborygmus. This lasted a short while and then the face became a deep red, relaxation occurred and usually the subject remained practically motionless unless disturbed by itching. About one fourth of the subjects slept lightly at some time during the test, sleep usually coming on about forty minutes after administration of the drug.

TABLE 1—Summary of Average Maximum Changes in Metabolic Rate and Body Functions Following Subcutaneous Administration of Placebo, Morphine and Dilaudid

Drug	Dose in Mg per Kg of Body Weight	Num- ber of Sub- jects	Respi- rations per Minute	Pulse Rate	Pulse Pressure Min of Mercury	Tem- pera- ture, °C	Basal Meta- bolic Rate
Placebo		10	+12	-32	-14	+0.7	+3.1
Morphine	0.14	10	-0.7	-14	-12	+0.01	-5.5
Morphine	0.22	10	-0.7	-27	-51	-0.12	-6.1
Dilaudid	0.01	10	-1.4	-78	0.0	-0.12	-7.0
Dilaudid	0.02	10	+0.6	-47	-24	0.0	-7.6
Dilaudid	0.03	20	-1.1	-12	-22	-0.1	-8.3

**Morphine Sulphate**—Morphine was administered to two groups of ten subjects. In the group receiving an average dose of 0.14 mg per kilogram of body weight, or a total of approximately  $\frac{1}{4}$  grain (10 mg), the average maximum depression in the metabolic rate for the entire period was minus 5.5 per cent. Within twenty minutes after giving the drug the metabolic rate dropped to an average of minus 3.7 per cent and then gradually fell to a level of 4.8 per cent after ninety minutes. It stayed near this level for the remainder of the experiment. Changes in the respiratory rate, pulse rate and pulse pressure were inconstant, some subjects showing an increase although in the majority there was a decrease. The temperature tended to increase slightly

from 0.1 to 0.3 degree centigrade in six subjects, but similar decreases in the others brought the average to a negligible amount. Tactile discrimination showed a slight but definite decrease in six subjects, no change in two and an increase in two.

The group receiving an average dose of 0.22 mg of morphine sulphate per kilogram of body weight (approximately  $\frac{1}{4}$  grain per subject) showed a slightly greater depression of the basal metabolic rate

Average maximum changes in basal metabolic rate after administration of placebo, morphine and dilaudid. Ordinate basal metabolic rate; abscissa, time in minutes. Broken line, dilaudid; chain line, morphine; straight line, placebo.

The rise noted at the period of ninety minutes may have been due to the fact that several subjects complained of slight itching at this time. The respirations tended to slow down somewhat, only three subjects showing increases of from one to three respirations per minute, with an average decrease for the group of 0.7 per minute. The pulse pressure dropped in all but two subjects resulting in an average decrease of 5.1 mm of mercury. While individual changes in the pulse rate and temperature varied, the tendency was toward a decrease. Tactile discrimination was uniformly decreased.

**Dilaudid**—Three ranges of doses were used for dilaudid. A small dose of 0.01 mg per kilogram of body weight (approximately 0.5 to 1 mg per subject) was given to ten subjects. With one exception, a maximum depression of the basal metabolism of from 5 to 13 per cent, with an average of minus 7 per cent for the two hour period, was noted. A gradual wearing off of the effect of the drug was evident and at the end of the test the average decrease was only 3.9 per cent. With this low dosage there was some tendency to depress the respiration, six subjects showing a decrease of from one to three respirations per minute. The average change in the respiratory rate was a fall of 1.4 per minute. A consistent decrease in the pulse rate varying from two to sixteen per minute was noted in all subjects, with an average decrease of 7.8 beats per minute. The pulse pressure increased from 4 to 10 mm of mercury in seven subjects, although this gain was offset by greater decreases of 10 to 14 mm of mercury in the other three. The temperature dropped from 0.1 to 0.5 degree centigrade in seven subjects, resulting in an average fall of 0.12 degree. Tactile discrimination was definitely decreased in all but two subjects, who gave unreliable readings.

A second series of ten subjects received a dose of 0.02 mg of dilaudid per kilogram of body weight (the average total dose per subject was 1.4 mg). Again, all except one showed decreases in the metabolic rate ranging from 6 to 19 per cent, with an average for the group of minus 7.6 per cent. This value would have been even greater had it not been offset by an increase of 14 per cent in one subject, who complained severely of itching. The failure of the average basal metabolic rate to drop further was undoubtedly due to the fact that most of the subjects experienced intense itching. With this group the respirations tended to increase, the pulse rate was decreased in all but two resulting in an average fall of 4.7 beats per minute, and the pulse pressure showed the slight average fall of 2.4 mm of mercury. Changes in temperature were inconstant. Tactile discrimination decreased definitely in all but one patient.

TABLE 2—Side-Effects Following Subcutaneous Administration of Morphine and Dilaudid

Drug and Type of Test	Number of Patients	Dose	Number Noting Symptoms							After Effects
			Euphoria	Itching	Vertigo	Nausea	Vomiting	Constipation	Diarrhea	
Morphine	10	0.14 mg /kg	2	4	8	4	0	5	0	1
	10	0.22 mg /kg	2	4	10	5	4	1	0	4
	5	¼ grain	1	2	5	5	4	3	1	2
	10	½ grain	8	6	7	12	3	6	0	4
	Total		13	16	30	26	11	15	1	11
Percentage			32%	40%	73%	63%	27%	37%		27%
Dilaudid	10	0.01 mg /kg	1	2	6	4	0	3	0	3
	10	0.02 mg /kg	3	8	4	12	0	2	0	1
	20	0.03 mg /kg	4	11	17	15	5	5	1	4
	14	0.01-0.04 mg /kg	2	8	8	8	4	3	1	4
	20	2 mg to each	3	10	10	14	6	9	4	10
Total	74		13	39	45	43	15	22	6	22
Percentage			17%	53%	61%	58%	20%	30%	8%	30%

A third group of twenty patients receiving a dose of 0.03 mg of dilaudid per kilogram of body weight (a total of 2 mg, the usual therapeutic dose) likewise showed inconstant changes for the individual body functions, although the effect in the majority was a decrease from normal. While a maximum increase in the metabolic rate of 3, 6 and 10 per cent was observed in three subjects, the others showed a decided decrease. In four patients a marked depression in the rate of 16, 19, 22 and 33 per cent respectively occurred. The average maximum decrease in the metabolic rate was 8.3 per cent. The changes in the other body functions were slightly more marked than those noted with the previous doses. A decrease in the respiratory rate ranging from one to three per minute occurred in fourteen subjects, but since an increase was noted in the others, the average decrease was only 1.1 per minute. In twelve subjects the pulse rate showed an average decrease of 6.8 but in the others increased an average of 4.4 per minute, resulting in an average change for the group of 1.2 less beats per minute. The pulse pressure decreased in thirteen of the twenty subjects, giving an average fall of 2.2 mm of mercury. The temperature likewise dropped in thirteen subjects, while the tactile discrimination was decreased markedly in every case.

#### SIDE-EFFECTS

Itching, perspiration or other symptoms were not noted in the group receiving placebos. Three subjects slept lightly during the experiments, while several noted transient vertigo on arising, due probably to prolonged lying in bed and increasing hunger.

In those receiving drugs the incidence of reported side-effects as shown in table 2 is higher than might otherwise be expected, since a special effort was made to note all untoward reactions whether severe or not. Since both drugs were used in therapeutic dosages and in nearly equivalent amount, the incidence of side-actions has been reported in the percentage of the total number of subjects receiving either drug. Euphoria, a difficult symptom to gauge, was considered to be present only when the subject strongly endorsed the immediate effects of the drug as decidedly pleasant. With larger doses of either drug, several subjects fell asleep and had fantastic dreams while others seemed content to remain and be tested for the remainder of the day. In five, priapism lasting an hour or more was noted. A sense of nausea while in a recumbent position was experienced by only eight, of whom one vomited. The high incidence of itching, particularly with dilaudid, was considered to be a result of drug action.

The fact that each subject was made to arise and walk home on completing the tests, usually at noontime, may have been a factor in causing nausea and vomiting in many. In a number, an attempt to eat lunch or drink coffee seemed to provoke these symptoms. Of the seventy-four subjects who were given dilaudid six complained of diarrhea during the night, while six others complained of severe pubic pain and inability to void for some time. Headache was noted in about a dozen subjects, most of whom had taken morphine. Dilaudid was given to seven girls and in four it caused severe reactions characterized by evidences of mental excitement such as crying, restlessness, nervousness and, in two, muscular cramps and tremors. Of the five girls who received morphine, only two showed similar unfavorable reactions.

#### TOXIC DOSES OF DILAUDID

Through error two subjects were given unusually large subcutaneous doses of dilaudid, one (J D R) receiving 13 mg and the other (P T M) 21 mg. The following observations were made:

The effects came on rapidly. Both patients became very sleepy and found it impossible to stay awake. Metabolism tests were taken for only an hour thereafter, J D R showing a decrease of only 8 per cent in the metabolic rate while P T M showed a decrease of 23 per cent. Intense itching caused considerable annoyance to both subjects and may have been responsible for the failure of the metabolic rate to decrease further. In P T M the respirations showed from 15 to 4 per minute within half an hour. After being observed for an hour, the subjects were made to arise and were taken home. Following attempts to drink coffee, both vomited and continued doing so for the rest of the day. P T M noting blood in the vomitus at times. They were greatly depressed and attempted to sleep, but their rest was periodically disturbed by nausea and vomiting and attacks of apnea and dyspnea.

At about 10 p m the symptoms subsided and they slept soundly until the next noon. The following day they felt very weak, tired and doxy and suffered from constipation but two days later they appeared to be none the worse for their experience. It is interesting to note that a few months later one fourth grain of morphine sulphate provoked considerable nausea and vomiting in both these patients.

## COMMENT

Because of the limited number of subjects used in this study and the unavoidable occasional variation in individual responses, it has been possible to show little more than the trend of the effect of the drugs on the various functions. It is apparent that both morphine and dilaudid lower the metabolic rate, as shown in the chart, generally in proportion to the dose given. In direct contrast, an increase in the metabolic rate was shown in the subjects of the control series. With dilaudid the metabolism is depressed sooner and to a more marked degree than with the supposedly equivalent doses of morphine. While it is stated<sup>9</sup> that "a dose of  $\frac{1}{32}$  grain (2 mg) of dilaudid is comparable to  $\frac{1}{6}$  grain (10 mg) of morphine sulphate and  $\frac{1}{20}$  grain (3.2 mg) to  $\frac{1}{4}$  grain (16 mg) of morphine" or, practically, that dilaudid is five times more active than morphine, our results indicate a greater difference. At least with respect to the effects on the metabolic rate, dilaudid appears more than ten times as depressant on the basis of dosage per kilogram of body weight. Unfortunately, it was impossible to estimate accurately quantitative changes in tactile discrimination, although the lowest dose of dilaudid used, 0.01 mg per kilogram of body weight, produced more loss of discrimination than morphine given in a dosage of 0.14 mg per kilogram of body weight.

Paine and his associates<sup>4</sup> state that dilaudid occasionally depresses the respiration markedly. We experienced in several subjects dangerous slowing of the respirations following therapeutic doses of both morphine and dilaudid.

## REPORT OF CASES

CASE 1—C K, a female medical student, aged 26, weighing 67 Kg, was given a 2 mg dose of dilaudid at 2:30 p. m. Within an hour she showed marked sleepiness, mental depression and slowing of the respiration from the normal rate of seventeen to three per minute. As collapse was feared after the respiratory rate had remained at this level for twenty minutes while the subject slept, she was aroused and made to walk. After drinking a cup of coffee she vomited several times and in a short while appeared to be less depressed. During the evening she was able to carry on her usual duties as clerk in a drug store.

CASE 2—B J M, a male medical student, aged 24, weighing 60 Kg, during a metabolism test after the small dose of 0.5 mg of dilaudid showed a depression of the respiratory rate from fifteen to six per minute, which lasted for nearly an hour.

Similar idiosyncrasies were noted with therapeutic doses of morphine, although the symptoms seemed to be more prolonged as shown in the following cases.

CASE 3—P D N, a medical student, aged 27, weighing 61 Kg, was given one fourth grain (0.016 Gm) of morphine sulphate during class at 2:30 p. m. Within two hours he was greatly depressed, very sleepy and showed a drop in respirations from seventeen to three per minute. After attempting to drink some bitter black coffee he vomited and became very weak. He was taken home and that evening, while in the care of several other students he fell asleep a number of times but had to be awakened each time because his respiratory rate fell to about three or four per minute. At midnight the patient was able to keep down some coffee and soon afterward seemed improved. He was allowed to sleep but was watched carefully and from then until noon the next day slept soundly.

CASE 4—H G E, female medical student, aged 22, weighing 53 Kg, received one sixth grain (0.01 Gm) of morphine in class and within an hour showed a transient depression of the respiratory rate from eighteen to five. During this time she voided incontinently, vomited three or four times and when

aroused for observations to be made by her fellow students, cried hysterically. Two hours after receiving the drug she was taken home and remained depressed during the evening. She vomited several times but showed no further respiratory embarrassment.

From these observations and, more particularly, from our experience with the two patients receiving toxic doses of dilaudid, we feel that dilaudid is slightly less depressant to the respiratory center than morphine.

With respect to the effects of these drugs on the circulation, Anderson<sup>7</sup> has shown that within an hour following the oral administration of therapeutic doses of morphine a very definite constant increase occurs in the pulse rate and the pulse pressure. We also have noted this phenomenon in a large number of our cases, but it occurred within twenty minutes following injection of either drug. After an hour, however, the full depressant effect of these drugs becomes evident and a definite drop occurs in both functions. The notable slowing of the pulse rate with the lowest dose of dilaudid (table 1) is probably a reflection of the depressant effect of the drug on the metabolism, lack of an appreciable stimulatory effect, and also the absence of itching.

Several factors seem to play a part in causing the general fall in body temperature observed after these drugs. With the lowered basal metabolism there is less heat production and also there is increased heat loss through dilated cutaneous vessels and through excessive perspiration.

In general, it is apparent that therapeutic doses of either morphine or dilaudid have little appreciable effect on the pulse rate, pulse pressure, respiratory rate and body temperature, although the tendency is toward a decrease from the normal level. While the changes occurring in the respiratory rate may be due to the depressant action of the drug directly on the respiratory center, it is felt that what changes occur in the circulation and temperature are secondary to the lowering of the basal metabolic rate.

In this study no consideration has been given to the habit-forming tendencies of the two drugs. However, we feel that since dilaudid compares favorably with morphine and offers the possibility of being less habit forming, it deserves critical clinical trial.

## SUMMARY

1 In normal subjects receiving placebos and tested over a period of several hours, the basal metabolic rate tended to rise with successive observations.

2 Morphine and dilaudid, administered subcutaneously in therapeutic doses, tend to lower the basal metabolic rate in proportion, usually, to the dose given.

3 Dilaudid acts more rapidly but over a shorter period of time than morphine.

4 While dilaudid is said to be about five times as potent as morphine, our results with respect to the effects on the basal metabolism indicate that it is at least ten times as active. We believe the recommended subcutaneous dose of 2 mg to be sufficient in ordinary cases and about equal to 16 mg ( $\frac{1}{4}$  grain) of morphine.

5 Tactile discrimination is decreased to a slightly greater extent by a dose of dilaudid (0.01 mg per kilogram of body weight) about one-tenth that of morphine (0.14 mg per kilogram of body weight).

6 Slightly less respiratory depression seems to result from dilaudid than from morphine.

7 Both drugs tend to cause similar slight decreases from normal in the heart rate, pulse pressure and temperature

8 Undesirable side-effects occur with slightly less frequency following the administration of dilaudid than after morphine Itching, however, seems to be a prominent complaint after dilaudid

ALUM-PRECIPITATED DIPHTHERIA  
TOXOID

THE RAPIDITY OF IMMUNIZATION FOLLOWING  
ONE DOSE

A E KELLER, MD  
AND  
W S LEATHERS, MD  
NASHVILLE, TENN

During the past few years the methods of immunization against diphtheria have been greatly improved Safe immunizing agents have been produced which contain a large amount of specific antigen, so that it is now possible to bring about a reversal in the Schick reaction from positive to negative in a larger proportion of individuals in a shorter period of time than by the older methods of immunization

The results following the use of toxoid in the prevention of diphtheria are well known Certain improvements in the production of toxoid have been made in an attempt to increase or concentrate the antigenic content and reduce the number of injections necessary to protect against infection Various substances have been added to toxoid with the idea of decreasing the rate of absorption from the site of injection and thereby producing a longer stimulation to the production of protective antibodies The most common of these substances has been some form of alum The work of various investigators who have used diphtheria toxoid treated with alum is covered in a recent report by Baker and Gill<sup>1</sup> Havens and Wells<sup>2</sup> reported that by precipitating toxoid with from 10 to 25 per cent of aluminum potassium sulphate the foreign protein content could be reduced to from 13 to 20 per cent of the amount it contained originally They were also able to protect guinea-pigs against 5 minimum lethal doses of diphtheria toxin by an injection of 0.1 unit of alum-precipitated diphtheria toxoid Subsequent reports by Graham, Murphree and Gill<sup>3</sup> show that, with one injection of 1 cc of alum-precipitated diphtheria toxoid containing from 5 to 10 antigenic units, 92.4 per cent of Schick positive children became Schick negative

This investigation was done to determine the rapidity with which a positive Schick test could be changed to a negative one in susceptible persons by the use of alum-precipitated diphtheria toxoid The toxoid used for this purpose was supplied by the state board of

health of Alabama and the Schick testing material was obtained from the state board of health of Massachusetts The same materials were used throughout for the original tests and the retests

In order to control these observations with preliminary Schick tests and repeated tests after the injections of the immunizing agent, children ranging in age from 4 to 19 years and residing in two institutions were tested with heated and unheated diphtheria toxin to determine the positive, pseudopositive, combined and negative Schick reactors Approximately 900 children were tested Of this number seventy-six, or 8.4 per cent, developed a positive Schick test, indicating a relatively low susceptibility rate on the part of the population tested It is not unusual to find such a small number of persons susceptible to diphtheria in institutions, owing to repeated exposure to and contact with persons harboring and discharging diphtheria bacilli from the upper respiratory tract It was found that those persons who were Schick positive had been in residence in these institutions for from one to five years The majority have lived in them more than two years It seems likely, therefore, that the positive reactors included in this report represent those persons who have been resistant to immunization through contact in the institution

The positive Schick reactors from each institution are reported separately as group A, consisting of fifty-three children, and group B, comprising twenty-three Each person was given one injection of 1 cc of alum-precipitated diphtheria toxoid subcutaneously in the deltoid region The members of group A were Schick tested twenty-two days after the injection Those remaining positive were retested sixty and ninety days later The plan of procedure was the same with the individuals in

Results Following One Subcutaneous Injection of 1 Cc of  
Alum-Precipitated Diphtheria Toxoid

Group A			
Total Number Schick Positive	Per Cent Schick Negative 22 Days After Injection	Per Cent Schick Negative 60 Days After Injection	Per Cent Schick Negative 90 Days After Injection
53	92.4	94.3	96.2
Group B			
Total Number Schick Positive	Per Cent Schick Negative 14 Days After Injection	Per Cent Schick Negative 28 Days After Injection	Per Cent Schick Negative 42 Days After Injection
23	60.0	95.6	100.0

group B except that the first retest was done fourteen days after the injection of alum-precipitated toxoid and those remaining positive were retested on the twenty-eighth and forty-second days The accompanying table shows the results following one subcutaneous injection of 1 cc of alum-precipitated diphtheria toxoid

In reporting the results of these observations we will give the data for all members of each group, as the distribution of males and females was approximately the same The results obtained following one subcutaneous injection of 1 cc of alum-precipitated diphtheria toxoid in these two groups of children indicate that a reversal of the Schick test from positive to negative may occur within a relatively short period of time

In group B, consisting of twenty-three children, 60 per cent were Schick negative fourteen days after the injection, while 95.6 and 100 per cent were negative

twenty-eight and forty-two days respectively after immunization

In group A, 92.4 per cent of fifty-three children were Schick negative twenty-two days after the one injection of alum-precipitated diphtheria toxoid. There were slight increases in the number of negative reactions obtained in this group sixty and ninety days after immunization, 94.3 per cent being negative after sixty days and 96.2 per cent after ninety days.

It should be noted that in one group 92.4 per cent were Schick negative after twenty-two days and in the other group 95.6 per cent were negative twenty-eight days following immunization. While the number of Schick negative reactions in both groups increased after these periods, for practical purposes an interval of from three to four weeks seemed to be sufficient to bring about a reversal of the Schick test in a large percentage of the children observed.

The local and general reactions following the injection of diphtheria toxoid were noted for forty-eight hours. The reactions following the injection of 1 cc of alum-precipitated diphtheria toxoid consisted of the usual symptoms that may appear following any similar procedure. In a majority of those receiving the injection there was no increase in temperature twenty-four hours later. Only five or six had temperatures of more than 100 F. The highest temperature recorded was 101.4 F. Those in whom there was an increase in temperature complained of headache, slight nausea and general malaise. These symptoms usually disappeared within forty-eight hours.

There was some local reaction in a large percentage of those receiving the precipitated toxoid. This, however, was not of serious nature and cleared up quickly. There was apparently no relationship between the amount of increase in temperature and the local reaction. In only one instance was the general reaction severe enough to require bed rest. No abscess formation at the site of injection occurred. In two instances the area of injection remained red, swollen, hot and moderately tender for several days but no suppuration occurred. In a majority of the individuals a small firm nodule could be felt at the site of injection. It is not unusual for such an indurated area to occur following other immunizing procedures, so that it is not surprising to have such a formation occur following the injection of precipitated diphtheria toxoid.

In comparing the results of these observations with those reported following the use of other immunizing agents against diphtheria we found that immunity is probably developed more rapidly following the use of one dose of alum-precipitated diphtheria toxoid. Harrison<sup>4</sup> has shown that, following three injections of 1 cc each of 0.1 L + diphtheria toxin-antitoxin mixture, 64 per cent of Schick positive children became negative from 122 to 203 days after the last injection. He has also reported that 95 per cent of a group of children were Schick negative from 90 to 133 days following two or three injections of commercial preparations of untreated toxoid.

White and Schlageter<sup>5</sup> using toxoid with 0.2 per cent alum and without alum prepared in the laboratories of Dr. William H. Park<sup>6</sup> have reported that 96.1 per cent of a group of children were immunized in two

months and 100 per cent in six months following two doses of 1 cc each of toxoid with alum, while 94.6 per cent of another group of individuals were immunized in two months and 95.9 per cent in six months following two doses of toxoid without alum. They also report that, following three doses of 0.5 cc each of toxoid with alum, 94.2 per cent were immune at two months and 96.1 per cent at six months. Following one dose of toxoid with alum, 50.8 per cent were immune in two months and 73.2 per cent in six months, while with one dose of untreated toxoid 49.2 per cent were immune in two months and 82.0 per cent in six months.

These data indicate that, while essentially the same results can be obtained in from two to six months with untreated toxoid and toxoid with 0.2 per cent alum, from two to three doses are required, whereas only one injection of alum-precipitated toxoid is necessary. The results following only one dose of toxoid with and without alum or three doses of toxin-antitoxin mixture are not as good as with one dose of alum-precipitated toxoid.

#### SUMMARY

The results obtained following the injection of one dose of 1 cc of alum-precipitated diphtheria toxoid indicate that immunity to diphtheria may be produced rapidly.

In one group of twenty-three Schick positive children, 60 per cent were Schick negative in fourteen days. In the same group, 95.6 per cent were Schick negative in twenty-eight days and 100 per cent in forty-two days after the injection.

In another group of fifty-three children, 92.4 per cent were Schick negative twenty-two days after receiving one injection of alum-precipitated diphtheria toxoid, 94.3 per cent were negative in sixty days, and 96.2 per cent were negative in ninety days after immunization.

The results following immunization with a single dose of alum-precipitated diphtheria toxoid compare favorably with those obtained following two doses of toxoid without alum or toxoid with alum and are much better than those reported following one dose of toxoid without alum and with alum or three injections of standard diphtheria toxin-antitoxin mixture.

**Headache**—The most important varieties of headache which possess somewhat distinctive characteristics are as follows. Nephritic headache—except the sudden attacks due to uremia—is in most cases caused by the arteriosclerosis which so often forms an essential part of chronic nephritis. The pain is apt to be of a throbbing character, somewhat shifting and often accompanied by vertigo and tinnitus. Headache from disorders of digestion and constipation is usually of a throbbing, pulsating character, it affects the frontal and orbital regions, and is made worse by sudden movements of the head. The headache of uterine diseases is usually occipital, sharp and radiating. Anemic headache is a sore and pressing pain, usually felt in the forehead and orbital region or in the vertex and is often associated with occipital pressure. As its name indicates, it is found in connection with the general and special forms of impoverished blood. In the typical headache of hysteria the patient feels as if a nail was being driven into the top of the head (clavus) but this type is of comparatively infrequent occurrence. The headache of neurasthenia, probably the most frequent of all headaches which require treatment, is of a pressing character, it is usually vertical, but is sometimes described as a band around the head. It is almost invariably worse in the morning becoming lighter or disappearing toward the latter part of the day.—Gordon, B. L. Importance of Cephalalgia in Ocular Diagnosis *Arch. ## Clinical Notes, Suggestions and New Instruments

### OTOGENIC TETANUS REPORT OF A CASE

HYMAN I VENER M D, AND ALBERT G BOWER, M D  
LOS ANGELES

Medical literature reveals that tetanus of otogenic origin is a rare occurrence, and when it does occur it is seldom suspected. Usually the underlying cause of the condition is trauma to the drum, a foreign body in the canal, or external irritation, all followed by a chronic suppurative otitis media or other suppurative process.

The following case was characterized by an acute onset, with death resulting in a very short time.

W S, a white boy, aged 4½ years, admitted to the hospital at 11 p m, Oct 14, 1932, had had a cold in the head for two weeks, with a discharging ear for the preceding five days, he had been unable to open the mouth for one day.

The parents stated that the patient had had a cold for about two weeks, which lasted until three days prior to admission. October 7 the right ear began to discharge and continued for five days. Except for buzzing in the right ear on the morning of admission, the patient presented no other complaint. On the date of admission he was taken to a clinic, where the examining physicians were unable to open his mouth, which they attributed to stubbornness, and made an appointment for him to return at a later date. The same evening the parents put the patient to bed at home, and half an hour later he got up, walked across the room and fell, his jaws locked, he choked several times and he turned purple. A physician in the neighborhood was called. He referred the patient to the hospital.

The recent past history was entirely negative. However, on detailed questioning, additional history was obtained from the parents as follows:

About six months before, a milk case fell on the child's head, making a deep gash on the scalp. The wound was treated with mercurochrome and healed without trouble. From time to time the child had gotten splinters in his hands while playing in the street, and the last incident of this type was about three weeks prior to admission. He also had had several scratches of the right heel, which troubled him some when putting on his shoes, but the duration of these scratches was unknown.

On physical examination the patient was breathing rapidly, the rectal temperature was 98.4 F, the jaws were tightly locked and the head was retracted.

The membrane of the right ear was ruptured and draining pus. The left ear was normal. The mouth could not be forcibly opened until 4 grains (0.26 Gm) of sodium amytal was given intravenously for relaxation. Examination of the throat was negative. The tongue, however, was scalloped and quite swollen, and the neck was rigid and spastic. The heart and lungs were normal, the abdomen was markedly relaxed and the spleen was enlarged a distance of 2 fingerbreadths below the costal margin.

Following the diagnosis of clinical tetanus, a cisternal puncture was performed, 25 cc of fluid being withdrawn. 60,000 units of tetanus antitoxin (previously warmed to body temperature) was allowed to flow in by the gravity method, and 140,000 units was given intramuscularly.

Seven hours following this therapy the temperature was elevated to 106 F and dropped to 104 four hours later and was associated with a pulse of over 180.

Eight hours following the cisternal and intramuscular injections, 150,000 additional units of serum was given intravenously, very slowly. After this procedure the temperature again became elevated to 107.6 F but gradually subsided to 103.

Death, which ensued thirty-six hours after admission, was due to both cardiac and respiratory failure. During the entire stay in the hospital, the respirations were rapid and shallow, the pulse was thready and rapid and the patient was cyanosed much of the time, so that an oxygen-carbon dioxide mixture was required at frequent intervals.

During the hospitalization period the patient received 32 grains (2 Gm.) of sodium amytal, subcutaneously, for sedation, an average of 4 grains every three hours.

The colloidal benzoin test was negative.

Report (by Dr Anson Hoyt of the pathology department) of the smears and culture from the draining ear, five days later, was as follows: *Clostridium tetani* (tetanus bacillus) was isolated from the culture from the right ear. This was definitely proved to be *Clostridium tetani* by mouse inoculation and by protection of a control with tetanus antitoxin.

### COMMENT

A clinical case of tetanus following an acute otitis media without any definite history of trauma to the ear was preceded by an acute infection of the upper respiratory tract.

It is possible that this patient may have been a carrier and that the acute infection of the upper respiratory tract activated and resulted in the clinical case as reported.

It is also conceivable that the splinters or the head injury previously mentioned might have played a role. This is purely conjectural, as the organism was recovered from the discharge from the ear.

1531 Purdue Avenue

### NEUTROPENIA FOLLOWING DINITROPHENOL WITH IMPROVEMENT AFTER PENTNUCLEOTIDE AND LEUKOCYTE CREAM

ELIZABETH N DAVIDSON M S AND MATTHEW SHAPIRO M D  
NEW YORK

Mrs M G, aged 31, admitted to the hospital, May 8 1934, had suffered from progressive pain with swelling in the gums and submaxillary glands for forty hours prior to admission. Two chills had occurred in the twelve hours previous to admission, and the temperature ranged from 101.6 to 102.4 F. She had vomited once on the day of onset and once the following day, and she was constantly nauseated.

She stated that on April 13 she had begun taking, under direction of a physician, sodium alpha-dinitrophenol in 100 mg capsules with meals, three times a day. According to her record of that date, her weight was 159 pounds (72 Kg), the temperature 98.6, pulse 80 and blood pressure 140 systolic, 96 diastolic. By April 24, she had lost 5½ pounds (2.5 Kg) and the record showed that the temperature was 98.6, pulse 104 and blood pressure 130 systolic, 90 diastolic.

She recalled that during the period while she was taking sodium alpha-dinitrophenol there had been three episodes of yellow tingeing of the sclerae, each lasting about two days. The urine had been a deep yellow brown at all times.

During approximately the last ten days before admission, nausea and diaphoresis had been observed frequently, together with a fever of 101 F. On both the third and the fourth day before admission the patient had attempted to take a capsule of the dinitrophenol but had vomited each time. Examination of her supply of remaining capsules of dinitrophenol and a record of the original number purchased revealed that she had taken 6 Gm in about twenty days plus 0.2 Gm, which she had attempted to take at the beginning of the present illness but had vomited. She had taken no amidopyrine nor barbiturates during that time.

On admission, the patient was obese and did not appear acutely ill. There was a yellow tinge to the sclerae. The mucosa of the nose and pharynx was inflamed and an ulcer was noted in the right posterior pharynx. There was a dark purple hue and swelling of the gums with hemorrhagic appearance, and whitish patches about a few teeth. There was swelling and tenderness on the left side of the mandible and in both submaxillary areas. The nodes of the posterior cervical chain were palpable and very tender.

Laboratory examination on admission showed red blood cells, 3,450,000, hemoglobin, 78 per cent, white blood cells, 1,100, with 1 per cent neutrophils, 4 per cent basophils, 12 per cent monocytes and 83 per cent lymphocytes. The blood culture was negative and bacteriologic examination of smears and

cultures from the throat indicated nothing of significance. The routine urine examination was negative and the nonprotein and urea nitrogen of the blood were both normal. The icterus index was 10, the direct van den Bergh test showed a delayed positive and the indirect a trace. Three days later the icterus index was 14.4, the direct van den Bergh test showed a delayed positive and the indirect a trace.

During the second day of hospitalization the urine showed an occasional specimen positive for alpha-dinitrophenol according to the indicator test. The Derrien test was also positive. The following twenty-four hour urine was negative to the Derrien test and slightly positive to the indicator test.

On the third day, May 10, a bromsulphalein test for liver function was performed and resulted in 70 per cent recovery thirty minutes after dye injection and 60 per cent recovery sixty minutes after dye injection. There was therefore evidence of impaired liver function.

The following day, May 11, the Derrien test of the urine was negative and the indicator test was impossible because of bromsulphalein interference. May 13 and 14, twenty-four hour urine specimens were again tested but were negative.

Therapy in part administered to the patient consisted of intramuscular injection of 10 cc of pentnucleotide given once on the day of admission, twice the second day, once the third day, twice the fourth day, twice on the fifth and once on the sixth day, making a total of nine injections.

As soon as the leukopenia was recognized it was decided to give a transfusion and to bleed a number of human donors for the preparation of leukocyte cream according to the method of Strumia.<sup>1</sup> Nine persons were bled for the purpose, about 300 cc being furnished by each one. Beginning on the day after admission and during the first week, from two to four daily intramuscular injections of leukocytic cream were given. They represent the preparations from a total of approximately 1,800 cc of whole blood. During the second week five small injections were given, the total of which had been prepared from 300 cc of blood.

One per cent plasma cells

The soporific and analgesic drugs used were codeine mainly, together with one dose each of acetylsalicylic acid, triple bromides and chloral hydrate.

The blood count was done twice daily, during the morning and afternoon at six hour intervals. On the second day the count revealed red blood cells 4,800,000, hemoglobin 86 per cent, platelets 240,000, and in the morning white blood cells 1,125, neutrophils 1 per cent, basophils 10 per cent, eosinophils 3 per cent, monocytes 12 per cent, lymphocytes 69 per cent,

<sup>1</sup> Strumia M M. The Effect of Leukocytic Cream Injections in the Treatment of the Neutropenias. *Am J M Sc* 187: 527-544 (April) 1934.

metamyelocytes 4 per cent, while in the afternoon, white blood cells 1,280, basophils 11 per cent, eosinophils 4 per cent, monocytes 25 per cent, and lymphocytes 60 per cent.

At no time during these observations was there an absence of granulocytes with the exception of the neutrophils. The percentages of eosinophils and basophils were increased. On the third day the total white count had dropped to 900 with no neutrophils and 1 per cent myeloblasts. The temperature of the patient was 104.4 F and her general condition was worse.

The fourth day, May 11, the white count doubled and almost tripled that of the preceding day and the neutrophils per cubic millimeter had risen to 52.5 in the morning and to 98.0 in the afternoon. On the fifth day only one observation was made,

Abridged clinical record of M G a woman aged 31 admitted at 12 30 p m May 8, 1934. The temperature is indicated by T. A transfusion of 500 cc was given at 6 20 p m May 8 followed by a moderate chill at 8 30. A blood culture taken at 1 p m May 8 remained sterile. The time of administration of the doses of pentnucleotide is indicated by the arrow points. Leukocyte cream (Strumia) was given by intramuscular injections the first dose at 12 17 p m, May 9, and a total of 14.5 cc in three doses on this day at the time indicated by the arrow points, 35 cc in four doses on May 10 and on following days as indicated. May 14 there were two injections, each of 9 cc. WBC shows the total count of white blood cells. The heavier line below it shows the count of polymorphonuclear neutrophilic leukocytes per cubic millimeter. The count of these cells May 8 was 11 at 1 30 p m and zero at 6 o'clock. May 9, it was 11 in the forenoon and zero in the afternoon. May 10 it was 9 in the forenoon and again zero in the afternoon. May 11 it rose to 52 at 9 30 a m and 98 in the afternoon. After this the increase of these cells was more rapid. Definite improvement in this respect was observed therefore about forty five hours after the first injection of the leukocyte cream.

at which time the white count was slightly lower, though the neutrophils were 130.5 per cubic millimeter. On the seventh day the patient was greatly improved, her temperature was normal, the morning count showed white blood cells 7,025 and neutrophils 3,442, and the afternoon count showed white blood cells 8,150 and neutrophils 3,505. From the eighth day to the day of discharge her white blood count ranged from 9,200 to 13,000 and the neutrophils from 5,327 to 8,580.

She received three intramuscular injections of leukocyte cream prepared from a total of about 300 cc of blood, on the second, fourth and seventh days after leaving the hospital. The white blood counts during this period were 10,350, 10,600, 17,000 and 8,750, with 43, 78, 57 and 58 per cent neutrophils, respectively. No abnormal white cells were observed.

The patient had a tonsillectomy in 1933 and has had for several years a definite pelvic infection with curettage in 1924 and unilateral salpingectomy in 1926. The present pelvic condition appears to require further surgical treatment. She stated that six months before her white count was found to be 18,000, with 70 per cent neutrophils. The initial symptoms of the dinitrophenol poisoning were attributed by the patient to the pelvic infection and consequently ignored by her.

COMMENT

Hoffman, Butt and Hickey<sup>2</sup> in a preliminary report have listed fourteen cases of neutropenia. Thirteen of these were fatal, and without exception the patients had ingested amidopyrine prior to their illness. The remaining patient recovered. This one had taken 100 mg of dinitrophenol four times a day for two weeks without other medication. This patient received roentgen and pentnucleotide therapy, as did several of the patients who died. The authors suggest the benzene ring as a common factor in these substances, "all of which have produced neutropenia experimentally or clinically."

<sup>2</sup> Hoffman A M, Butt E M and Hickey N G. Neutropenia Following Amidopyrine. *J A M A* 102: 1213-1214 (April 14) 1934.

Our case, with the exception of the positive finding of lymphadenopathy, resembles the eight cases reported by Rosenthal,<sup>3</sup> which he termed "leukopenic infectious monocytosis," a benign form of agranulocytosis. One of his patients had arspenamine therapy and in the remainder an exogenous toxic factor was ruled out and the cause was assumed to be bacterial. He found monocytosis to be from 14 to 66 per cent, together with a leukopenia of from 900 to 4,200, and neutropenia. Our case showed a monocyte percentage of from 6 to 44.

We feel that there is evidence of dinitrophenol poisoning in this case, since the indicator test showed the presence of dinitrophenol and the positive Derrien test, according to the report of Perkins,<sup>4</sup> indicated dinitrophenol intoxication.

Since the use of dinitrophenol seems to be increasing from the time of its clinical introduction as a metabolic stimulant by Cutting, Mehrtens and Tainter,<sup>5</sup> the need for vigilant supervision of the patient taking this drug requires emphasis. Individual reactions together with their symptoms seem to be exceedingly variable. The record of our patient suggests the wisdom of frequent blood counts during the administration of drugs of this type. Early recognition of a leukopenia may avert an impending tragedy.

303 East Twentieth Street

ANURIA FOLLOWING DIABETIC COMA RELIEVED  
BY HYPERTONIC SALT SOLUTION

HOWARD T. ROOT, M.D., BOSTON

Deaths from diabetic coma frequently are accompanied by anuria developing from six to twelve hours before death. Such anuria in the aged patient is sometimes due to chronic nephritis. In the young it is usually regarded as due to renal block brought about by the acidosis and the fall in blood pressure. In certain cases vomiting, especially in children, may continue after acidosis, as indicated by the presence of diacetic acid in the urine, has disappeared. The renal irritation, due to diabetic coma and shown not only by the typical coma casts but also in many cases by leukocytes and even red blood cells, may persist and indeed may explain the vomiting, as in the first case to be reported. However the microscopic observations in the urinary sediment are interpreted, the effect of dehydration and loss of chloride due to frequent vomiting must not be overlooked. It is important to investigate the level of the plasma chloride in

Relief of Anuria in Diabetic Coma in a Girl, Aged 7 (Case 1)

every case of anuria, since in some instances the administration of hypertonic salt solution is actually life saving. The following three cases illustrate its value.

REPORT OF CASES

CASE 1.—In a schoolgirl, aged 6 years and 11 months, diabetes developed in December 1933. She entered the New England Deaconess Hospital, December 23, with beginning coma. The

3 Rosenthal Nathan. Leukopenic Infectious Monocytosis (Benign Form of Agranulocytosis). Libman Annals Vols 3 1003 1027 1932

5 Cutting W C, Mehrtens H G and Tainter M L. Actions and Uses of Dinitrophenol Promising Metabolic Applications J A M A 101 193 195 (July 15) 1933  
From the George F Baker Clinic of the New England Deaconess Hospital

skin was dry. She had Kussmaul respiration. The lips were cherry red. The urine contained 36 per cent sugar and 3 plus diacetic acid as well as a trace of albumin, many red blood cells, leukocytes and a few granular casts. The blood sugar was 0.32 per cent. Acidosis was not far advanced and with 13 units of insulin during the night the urine became sugar free. However, the next morning the sugar returned. On that day she had 14 units and on the following day she again had 14 units. Vomiting began December 26, and the urinary output from December 26 to December 27 fell to 175 cc. From December 27 to December 28 only 360 cc of urine was excreted and she vomited 360 cc. December 28 only 15 cc of urine was obtained. That evening at 7:30 p m she became cyanotic and stopped breathing, and Jacksonian convulsions developed. During the next three hours she had generalized convulsions and was given the following treatment:

- 1 Thirty cubic centimeters of 50 per cent dextrose solution intravenously
- 2 One cubic centimeter of epinephrine hydrochloride, 1 1,000
- 3 One-sixth grain (0.01 Gm) of morphine
- 4 Caffeine sodobenzoate, 3/4 grains (0.24 Gm)
- 5 Salt solution, 500 cc subcutaneously
- 6 Ten per cent salt solution, 10 cc intravenously

At 11 p m the blood sugar was 0.57 per cent, the plasma chloride was 463 mg and the nonprotein nitrogen was 126 mg. During the succeeding day no urine was obtained and at noon the nonprotein nitrogen was still 118 mg. At 4 p m, therefore, she was given 50 cc of 10 per cent salt solution intravenously and within one hour she voided 2 ounces (60 cc) of urine. From that time on she voided normally and the nitrogen of the blood fell to normal on December 31. She left the hospital, January 11, on a diet of 169 Gm of carbohydrate, 75 Gm of protein and 85 Gm of fat, a total of 1,741 calories, and 16 units of insulin daily. A blood sugar test was 0.08 per cent at 11 o'clock in the morning. April 16, 1934, she was in excellent condition, and the urine was free from albumin, blood, pus and casts.

CASE 2.—A man, aged 24, in whom diabetes had developed in October 1931, entered the Miami Valley Hospital in Dayton, Ohio, at 5 p m, December 20, in diabetic coma. He had felt weak and drowsy for ten days, had broken his insulin needle and had omitted insulin. Respiration was Kussmaul in type. The skin was dry. He received 215 units of insulin between 5:45 p m and midnight and 280 units during the next day. Anuria developed at 2 a m, December 21. He was given 50 cc of 50 per cent dextrose because of a blood sugar that had fallen to 0.087 per cent. Anuria continued, until December 22 he was given 60 cc of 10 per cent saline solution intravenously twice. At this time the blood urea nitrogen was 60 mg and the blood creatinine was 5.45 mg. Following the administration of the hypertonic salt solution he passed 930 cc of urine that day and thereafter his recovery was uneventful, although the blood urea nitrogen was still 60 mg on December 27. January 4, however, the blood urea nitrogen had fallen to 18 mg and the creatinine to 1.6 mg. He was discharged from the hospital, Jan 26, 1933, in good condition, having been sugar free from December 28 to that day.

CASE 3.—A woman, aged 48, entered the Brattleboro Memorial Hospital, Jan 5, 1934, in diabetic coma, following three days of vomiting and diarrhea. During the first twenty-four hours she received 150 units of insulin and thereafter from 20 to 65 units daily. In spite of daily administration of salt solution subcutaneously, from 1,500 to 3,000 cc, some vomiting and diarrhea continued, and the urinary secretion fell to an average of 150 cc daily. General edema developed, but the patient became anuric on January 11. On this date the nonprotein nitrogen of the blood reached 120 mg per hundred cubic centimeters. Sixty-five cubic centimeters of 10 per cent saline solution was given intravenously and only 335 cc of urine was obtained. A second injection of 65 cc of 10 per cent saline solution was followed by improved urinary secretion, so that during the next five days the urinary output varied from 1,650 to 2,340 cc. She later died from carcinoma of the rectum.

1 Reported through the courtesy of Dr Benedict Olch, Dayton, Ohio.  
2 Reported through the courtesy of Dr Chester Leach and Dr E P Joslin.

COMMENT

The most important point in these cases, as in the case of a 5 year old boy previously reported,<sup>3</sup> is that salt solution given under the skin and dextrose solution given either under the skin or intravenously failed to produce urinary secretion. When such treatment fails, the physician is apt to consider that nothing more can be done. An analysis of the plasma chloride may then show a low value, which clearly indicates the lack of chloride. In case 1, in a child, the first dose of 10 cc of 10 per cent sodium chloride solution was ineffective because the amount was too small. Usually 50 cc of such a solution is necessary, and in cases 2 and 3, in adults, totals of 120 and 130 cc, respectively, of 10 per cent salt solution were needed.

A CASE OF PENTOSURIA OF THIRTEEN  
YEARS STANDING

S R SALZMAN MD TOLEDO OHIO

In their article on pentosuria with a report of twelve cases, Enklewitz and Lasker<sup>1</sup> called attention to the infrequency with which this diagnosis is made. These authors give a summary of the diagnostic data together with chemical studies of the pentose bodies.

The point of interest in the case reported here is the known presence in the urine of a reducing substance for a period of thirteen years, which was finally shown to be pentose. Except for the presence of this reducing body in the urine, the patient is in excellent health.

REPORT OF CASE

F M S, a girl, aged 17 years, of Jewish parentage, was 5 feet 3½ inches (161 cm) tall and weighed 115 pounds (52 Kg). Except for whooping cough at 16 months she was in good health until the age of 4½ years, when persistent infection in the tonsils resulted in their removal. At the time, sugar was found in the urine. She was put under the care of a pediatrician of national prominence in a large city. She was hospitalized for ten days. The reports of this period of study are not available but it is known that the reducing sub-

Laboratory Data

Date	Diet	Urinary Sugar 24 Hour Quantity	Blood Sugar Fasting	Blood Sugar 1 Hour After Dextrose
3/13	Protela 45 Gm Fat 90 Gm Carbohydrate 75 Gm	2 Gm	0.98	
3/17	Protela 45 Gm Fat 90 Gm Carbohydrate 60 Gm	3.11 Gm	0.100	
3/20	Protela 45 Gm Fat 90 Gm Carbohydrate 100 Gm	2.2 Gm	0.100	
3/24	Protela 45 Gm Fat 90 Gm Carbohydrate 1.0 Gm	2.1 Gm	0.100	
3/25	50 Gm of dextrose	Trace	0.94	112

The concentration of the sugar in the urine varied from 0.4 to 0.7 per cent.

stance was thought to be dextrose, and a diagnosis of renal diabetes was made.

No further attention was given to the problem, and the diet was unrestricted.

In March 1926, at the age of 9, she was again hospitalized because of numerous furuncles on the back and in the axilla. These cleared up promptly after surgical attention.

The laboratory data of the study made at this time at St Vincent's Hospital is given in the accompanying table. It will be noted that all the blood sugar determinations were normal and that the output of the reducing substance was unrelated to the carbohydrate in the diet. The quantity was fairly constant and was highest during the time the patient was on the low carbohydrate diet.

J Root, H F and Henson P D Postoperative Suppression of Urine Relieved by the Intravenous Injection of Hypertonic Salt Solution J. A. M. A. 97: 540 (Aug. 22) 1931  
1 Enklewitz Morris and Lasker Margaret Studies in Pentosuria Am J. M. Sc. 186: 539 (Oct.) 1933

The reducing substance in the urine was again reported as dextrose. The diagnosis of renal diabetes was made, and no dietetic restrictions were imposed.

The patient remained in good health, except for an attack of measles, until December 1932. Following exposure at a football game, lobar pneumonia developed, from which she made an uncomplicated recovery. Sugar was noted in the urine throughout the illness but was not increased in quantity.

Following the publication of the article on pentosuria<sup>1</sup> a study of the urine was again undertaken. The twenty-four hour quantity obtained was 760 cc and contained 0.4 per cent sugar, a total output of 3 Gm for twenty-four hours.

A positive Bial test was obtained. A portion of the urine was then fermented for forty-eight hours and again tested. The reducing substance was still present in the same percentage, and again the Bial test was positive. It reduced Benedict's solution in the cold at room temperature after several hours.

It can be safely assumed that the substance present in the urine is a pentose and the original assumption that it was dextrose was in error.

After at least thirteen years of pentosuria the patient is in excellent health and her physical development has been in no way retarded. That pentosuria is essentially a harmless anomaly of metabolism may be presumed, and the importance of its recognition from the standpoint of prognosis as well as from the standpoint of the insurability of the individual should be stressed.

1708 Jefferson Avenue

DRUG ERUPTION DUE TO QUININE RECURRENCE  
FOLLOWING USE OF CONTRACEPTIVE

WILLIAM K FORD, MD ROCKFORD ILL

E W D, a man, aged 26, consulted me, Nov 16, 1933, because of a vesicular dermatitis accompanied by intense itching of the scalp, face and neck of thirty-six hours' duration. The eruption began within twenty-four hours after two applications of Kreml hair tonic and consisted of tense, acuminate, split pea sized vesicles filled with a clear to straw colored fluid. There was edema of the scalp and eyes. November 17 his face became swollen and he had nausea, abdominal distress and loose stools.

The patient refused to have a patch test of the hair tonic but agreed to patch tests of the various ingredients. The manufacturer supplied a list of the ingredients and the patch tests were applied to the inner surface of the right arm. The patch containing 39A alcohol (18 Gm of cinchonidine sulphate to 1 gallon of isopropyl alcohol) gave a definite papulovesicular reaction on an erythematous base which was limited sharply to the area of the patch. Patch tests were then applied containing isopropyl alcohol and dilute quinine sulphate. The test for quinine responded with a marked vesicular eruption, which spread over the entire arm and forearm and was similar to the dermatitis of the face and scalp. The patient was dismissed with a warning regarding the use of quinine.

March 23, 1934 he returned with an edematous vesicular dermatitis involving the penis, scrotum, eyes, cheeks, ears and sides of the neck. He stated that his wife had used a contraceptive (vaginal suppository) the evening of March 20 and that early the following morning he awoke with a severe itching of the scrotum and penis which were fiery red and swollen. In the afternoon of March 21 the eruption appeared on the face involving the same areas that had been affected following the use of the hair tonic. The eruption was accompanied by a diarrhea for two days.

Investigation revealed that the contraceptive contained quinine bisulphate and boric acid in a base of oil of theobroma.

COMMENT

A case of dermatitis venenata in a patient known to be sensitive to quinine, followed the use of a contraceptive suppository containing quinine bisulphate.

CONCLUSION

Contraceptives must be added to the list of causes of dermatitis venenata in cases of obscure etiology.

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, MD  
CHICAGO

*NOTE—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed*

#### FEVER REGIMEN

Unless excessive, pyrexia is beneficial to the organism attacked by microbial invasion.

The first aim in the treatment of all fevers is causal therapy, i. e., the discovery of the nature of the exciting cause, and the application of whatever specific remedy there may be to jugulate it. Still, no matter what the name or nature of the causative organism is, the care and general management (regimen) of all fever patients is essentially the same.

#### REST

Complete rest in bed is indicated by even the most moderate degree of pyrexia, for it means (aseptic fever excepted) that the system is engaged in a conflict which, no matter how seemingly insignificant at the beginning, may assume serious proportions, either because of inadequate mobilization of defensive forces in the early stages of the fight or because of secondary invasion by other foes. Indeed, in apyrexial and hypopyrexial infections with a tendency to chronicity, the therapeutic induction of fever (pyretotherapy) is indicated. Whenever, therefore, the body temperature (whether registered by mouth or by rectum) does not go below 99 F some time during the day or exceeds 99.5 F at any time of the day, fever regimen should be instituted.

Complete rest means more than merely going to bed. It means securing a person (a nurse) to take care of the patient. It means making the patient comfortable in bed, which is an important part of the art of nursing. It means the use of a urinal and bed pan. It means securing an abundance of fresh air by appropriate ventilation. It means protection against chilling, which is most especially liable to occur when the temperature drops suddenly and the patient is drenched in sweat, when the fever patient leaves the bed for any purpose whatever, and when he is permitted to be in garments wet from involuntary urination. The prevention of bed sores (q v), the daily cleansing bath, the alcohol back rub, the occasional changing of position (to prevent hypostatic pneumonia), especially important in the mentally or physically depressed patient, are items so well taken care of by the average trained nurse that the young physician is liable to forget ordering them when a case must be managed without such trained help.

Mental rest also must be enforced. This does not necessarily mean condemning the patient to absolute inactivity. There is occupation therapy appropriate to the fever patient to be resorted to when the temperature is not high, the mind is clear and the patient is quite free from suffering. It must take cognizance of the fatigability of the fever patient's nervous system, must

avoid increased heat production by not requiring movement of large muscle groups, and above all must not interfere with the principle of immobilization of infected tissue. It is only by means of suitable occupation therapy that patients can be kept happy and contented in bed such conditions as tuberculosis or endocarditis. Excitement, anxiety and worry must be eliminated as far as possible. This can best be secured by tactful exclusion of visiting, with only such exceptions as may be conducive to the patient's peace of mind.

Securing adequate sleep is an essential part of this regimen. As a rule, fever patients do not sleep well or for many hours at a stretch. They should be permitted to sleep as much during the day as they possibly can. Enforcing hours of quiet for this purpose may render unnecessary the always more or less objectionable administration of hypnotics. Nevertheless, one must not go to the extreme of failing to give an appropriate hypnotic (see Insomnia) when the patient does not secure sufficient sleep in the twenty-four hours for how much sleep the patient has had during the early days of his sickness may become of as crucial importance to ultimate recovery as how much food he has digested. A patient who is delirious or who may become delirious must never be left alone, even for one minute. In such cases two attendants are required. If this is impossible, the patient should be protected by bed rails against falling out of bed and kept by straps to the wrists and ankles from getting out of bed.

#### ALIMENTARY HYGIENE

The febrile anorexia may be humored for the first day or two. Then comes the time, if the fever shows a tendency to continue, when skilful feeding to maintain optimal nutrition in spite of the febrile impairment of digestive function comes to be of great importance. Now appetite is a luxury, not a necessity. For a critical stage may have to be passed through when digestive and circulatory functions are at such a low ebb that feeding may need to be all but discontinued.

*Administration of Fluid*—A liberal fluid intake is of the utmost importance throughout the course of fever. Fluid should be administered so frequently, as not only to quench but even to prevent the fever patient's proverbial thirst and to keep his tongue moist. It may be taken as an axiom that whenever the patient's mind is clouded he will not be given enough of that which he needs most, namely, water, unless special provision is made for it.

There is no substitute for fresh cold water as a thirst quencher unless it be carbonated water, which is likely to be more efficient because it stimulates the stomach to empty itself. The administration of carbonated fluid is a help in securing more rapid water absorption that should be invoked whenever possible. It is contraindicated by gas distention of the abdomen or by weakness of the heart.

The test whether the patient receives enough fluid is the quantity and color of the urine. The quantity should be recorded as a routine in all very sick patients and maintained above 1,000 cc in the twenty-four hours, which should always be possible unless the kidney itself is diseased.

When enough fluid cannot be given by mouth, retention enemas of fluid, preferably rendered isotonic by the addition of 5 per cent corn syrup, should be resorted to unless these are contraindicated by necessity for complete enteric rest, as in peritonitis or diarrhea.

When neither oral nor rectal administration is adequate, some form of injection of fluid becomes imperative, and whether this is to be by hypodermoclysis or phleboclysis or possibly, in children, by intraperitoneal injection will depend on the urgency of the indication. Phleboclysis is the only method whereby an adequate parenteral intake of fluid can be maintained for any length of time. These injections should not be withheld until an emergency exists but rather used to prevent emergencies. They should be resorted to as soon as there is an obvious threatening of fluid deficit that cannot be overcome by simpler means. Their prompt and adequate use may save life. The choice of the fluid to be injected depends on the following considerations:

(a) Five per cent dextrose solution is the standard injection fluid to antagonize hypohydration.

(b) Five per cent dextrose in physiologic solution of sodium chloride should be employed whenever there is hypochloremia, but only until this is corrected. Continuous injection of this solution introduces an excess of salt into the system.

(c) Ten per cent dextrose solution is the one to be injected when parenteral supply of carbohydrate as well as of fluid is required.

(d) Twenty-five per cent dextrose solution, in amounts of from 10 to 20 cc given very slowly every few hours, is to be employed when the heart is failing because of prolonged malnutrition or when dextrose is indicated but the heart is too enfeebled to permit of bulky injections.

**Amplified Milk Diet**—Considerations as to Quantity. After the first few days, during which the patient's anorexia may be respected and the patient be given only as much as he cares to take, the diet should be progressively increased—signs of digestive disturbance always being watched for—until the caloric intake is adequate for the needs of the patient. This should, at its minimum be 30 calories per kilogram in the twenty-four hours. A temperature averaging 102 F adds about 25 per cent, i. e., increases it to about 40 calories per kilogram, still higher fever may add 50 per cent. Hence an adult weighing 70 Kg (150 pounds) needs at least 2,100 calories, but generally 3,000 calories in twenty-four hours. A protein income of from 65 to 80 Gm having been provided the remainder is made up chiefly of carbohydrate. Fat is not well taken care of in fever.

An exclusive milk diet is not adequate to provide such an intake. The caloric value of 1 liter of milk is 700, so that 4 liters (1 gallon) would be required to yield 2,800 calories, a quantity that it is obviously impossible to ingest in the twenty-four hours. The most a fever patient can ingest of milk is 2 liters in the twenty-four hours which at feeding intervals of three hours would require the administration of 250 cc (a large tumblerful) at a time. This would take care of the protein requirement (1 liter of milk = 30 Gm of protein, 2 liters = 60 Gm) and of about one-half the caloric intake (1,400 calories).

Addition of carbohydrate to the extent of 400 Gm renders the diet adequate ( $400 \times 4 = 1,600$ ). A 40 Gm slice of toast adds about 100 calories, so does a serving of oatmeal or other gruel or of pudding. Eating four crackers yields a similar amount. If the patient receives—to make calculation easy—one such 100 caloric addition with each of his eight milk feedings 800 calories of the deficit will have been taken care of and it will still be necessary to provide about 800 calories

to yield an ample (3,000 caloric) diet. If this is introduced in the form of sugar or of lactose (1 teaspoonful = 5 Gm = 20 calories), 40 teaspoonfuls will be required, a rather large amount to be disposed of. Some of this sugar may be given with the drinks. A tumblerful of orangeade is worth about 100 calories. Lemonade sweetened with  $2\frac{1}{2}$  teaspoonfuls of sugar yields 50 calories. If the patient is given six fruit drinks (lemonade and orangeade alternating) every three hours alternating with his feedings, 450 calories can be disposed of. Lactose, less sweet than sugar, may be added to milk (lactose milk, two teaspoonfuls per tumblerful), and sugar may be used to sweeten milk toast or cereal gruel.

The moderate use of fat makes the problem of adequate feeding of the fever patient a practical possibility. One egg adds 70 calories (and seven and one-half eggs yield the amount of iron<sup>1</sup> required in the twenty-four hours), two slices of crisp bacon yield 70 calories, and so do one square of butter or of margarine and two tablespoonfuls of cream. A serving of ice cream is worth 200 calories. One tumblerful of "special" eggnog 180 cc of milk (= 126 calories), two eggs (= 140 calories) and two tablespoonfuls of molasses (= 84 calories) yield 350 calories. But it is rather difficult to digest.

Considerations as to Quality. It goes without saying that only the best quality of food may be served to patients. "Spoiled" food, which may produce a transient illness in a well person, may kill a fever patient. Furthermore, food must be palatable and varied. This means that milk should not always be served plain but also as buttermilk, that it may be flavored with "malted milk" or with cocoa (which also adds to the caloric value, 1 cup of cocoa = 200 calories), or with coffee or tea (which lessen it). It may be served in the form of eggnog or of cream soups. It is evident that the skilful administration of an adequate, enjoyable and digestible diet to the fever patient is an important item in the art of nursing and that the longer the fever lasts, as in typhoid, tuberculosis or endocarditis, the greater the responsibility devolving on the nurse as well as the physician to maintain as good a state of nutrition as possible.

It is not necessary that the fever patient be plied with cold food exclusively. He may have, for instance, hot broth in which one or two well beaten eggs may be stirred, or to which croutons (small cubes of toast) may be added, to make it nutritious.

As long as the fever patient's mouth is dry, it is customary to prescribe only liquid or soft food. As soon as the salivary glands have recovered their activity, as indicated by the tongue being moist, dry toast, zwieback and crackers, poached or scrambled eggs, tender meats and other food that requires chewing may be added, thereby greatly facilitating adequate caloric intake.

Coffee and tea may be useful not only as flavoring for food but also as stimulants to the circulation. A cup of hot, black coffee may help a fever patient who is dully or shivering after a cold bath, but it should not be used for this purpose at bedtime, as it may make the patient restless and sleepless. At that time a hot "toddy" with alcohol is better.

Alcohol occupies a position somewhere midway between a dietetic article and a drug. In the therapy

<sup>1</sup> Two liters of milk furnishes less than one-fourth the required amount of iron.

of fever patients it may be employed in one of four different ways, but it should be given only when and as indicated and not in a routine manner

(a) For its caloric value (1 cc = 7 calories) in the alcohol addict, to whom it needs to be given from the very first in liberal doses (possibly 250 cc or even 500 cc) of whisky or brandy or "cologne spirit" Addiction and fever both increase the degree to which alcohol is oxidized and acute disease should never be taken as the opportunity to break a drug habit. Such an attempt may cost the patient's life. In patients difficult to feed, most especially the aged, smaller doses (from one-half to one tablespoonful of brandy or "cologne spirit" every two to four hours) may be given with food.

(b) For its stomachic value and the flavoring of food, in the form of wine or brandy (teaspoonful to tablespoonful) added to milk or egg-nog.

(c) For its narcotic value, to lessen restlessness, sleeplessness or delirium. When the alcoholic addict develops fever he is very prone to delirium, which may require a more powerful narcotic (e. g., paraldehyde).

(d) As a "diffusible" stimulant to the circulation when required to bring blood to the skin, before or after cold hydrotherapy, or both, in the form of from 25 to 50 cc of wine, 15 cc of brandy (or "cologne spirit") in a wineglassful of water, or from 4 to 8 cc of aromatic spirit of ammonia also in a wineglassful of water.

*Care of the Mouth*—The mouth of the fever patient must be thoroughly cleansed after each feeding. Warm water is the essential thing for this purpose. "Mouth wash" is merely "flavoring" but it makes the procedure more pleasant. Solution of Hydrogen Dioxide, diluted with an equal amount of warm water, helps in cleansing a mouth that is in bad condition. If the patient is too sick to brush his teeth, the nurse must do it for him. A short piece of whalebone (or similar material) around which a pledget of gauze is wrapped dispenses with the necessity of employing the gauze-wrapped finger. False teeth should be kept out of the mouth until the patient receives diet that requires their use, then they should be removed between feedings, cleansed and kept in cold water. The lips of all fever patients should be kept anointed with cold cream or petrolatum. The appearance of sordes, the presence of a heavily coated dry tongue, or a foul mouth reflect on the quality of the nursing care and bring with them danger of painful fissures and ulcers that may make feeding difficult and proper cleansing impossible, and invite infection of salivary glands and even of the middle ear and possibly the mastoid.

When the physician at each visit looks at the patient's tongue, as he always should, he gathers indications not only as to the state of the patient's general condition and the kind of diet that will probably be tolerated but also as to the kind of nursing care he is receiving.

*Care of Intestine*—It is the physician's duty to see to it that the food administered is properly digested and its residue adequately eliminated. It is the nurse's duty to keep the physician informed on how well these functions are performed not only by recording the number of stools each day but also their character, if there is any departure from the normal.

When the fever patient's diet is well digested there is a tendency to constipation, which is best corrected by adding cooked fruit and vegetable purees.

When diarrhea is present, the first thing to do is to revise the diet in accordance with the principles laid down in connection with the Therapy of Diarrhea (q. v.). The same is true of tympanites (q. v.). The physician should regularly inspect and palpate the abdomen to detect, at the earliest possible moment, appearance of tympanites and the accumulation of fecal masses.

Physic should not be ordered as a routine but only as and of the kind required. Whenever rectal examination reveals the presence of scybala in the ampulla, an evacuant enema is indicated. If the stools are dry and hard, Liquid Petrolatum (one tablespoonful at bedtime or morning and evening) or a Petrolatum Emulsion (if the patient objects to the oil) should be ordered. The bed patient's tendency to colon atony is best antagonized by stimulants to peristalsis, e. g., Aloe Pills (one or two at bedtime) or Cascara Sagrada (fluidextract, from one-half to one teaspoonful at bedtime, the Aromatic Fluidextract of Cascara Sagrada to be preferred for women and children). Salines, so frequently ordered for bed patients, are less desirable because they do not adequately stimulate peristalsis.

#### ANTIPYRESIS

Antipyresis is indicated only when the body temperature exceeds 105 F in a fever with a relatively short course, such as pneumonia, or 103 F in a prolonged febrile disease, such as typhoid, because such temperatures are in themselves detrimental to the tissue cells. For the reduction of such excessive temperatures, appropriate hydrotherapy offers the only method of real advantage to the patient. Even if these temperatures are not reached, fever patients should from time to time, say, twice daily, be bathed with cool water so as to be refreshed, just as healthy persons refresh themselves by a cool plunge on a hot summer day, and a restless and sleepless patient might be given a cool pack to comfort and quiet him. Indeed, the main object of hydrotherapy, even when the temperature is excessive, is not mere reduction of temperature but improvement in the febrile disturbances of the nervous system and the circulation, the stimulation of respiration and of kidney elimination and, what is most important, the raising of metabolic activity and the increasing of resistance to infection. The latter effects of hydrotherapy may be compared to "opening the drafts so as to permit the fire to burn more briskly."

The essential thing to remember in attempting reduction of excessive fever temperature is that it is not merely a matter of simple temperature equalization between a hot body and a cool medium but a matter of circumventing the heat-regulating mechanism, which tends to maintain the fever temperature by the same means by which normal body temperature is maintained, namely, by peripheral vasoconstriction and increased metabolic activity. The peripheral vasoconstriction must be antagonized, so as to bring the hot blood from the interior of the body under the influence of the cooling medium, this is generally accomplished by appropriate covering in the "packs" or by vigorous rubbing in the baths. By such means these procedures are made less disagreeable as well as more efficient, not only by exposing the blood to the cooling influence but also by preventing shivering with its excessive heat production. During the procedure the skin must be kept red as constantly as possible, and, at the end of it, left red, warm and moist, i. e., in the best condition for heat elimination. If the skin is permitted

to stay pale during the bath and allowed to remain pale and cold at its conclusion, the patient feels miserable and shivers, and presently the temperature may be higher than it was before the bath.

*The Choice of the Antipyretic Procedure* — This depends on the condition of the skin, of the general circulation, of the kidneys, and of the nervous system.

When the skin is hot and dry, reduction of temperature is relatively easy, mere moistening with tepid water (85 F) will give the patient comfort. When the skin is cold, the blood must be made to flow into the skin by preliminary use of heat (105 F) with friction or, if this fails, by a mustard pack or bath, supported by a stimulant to the circulation (coffee or alcohol). Cold should never be applied to a cold skin.

The feebler the circulation, the gentler must be the procedure. One should beware of using heroic hydrotherapy in a collapsed patient, even if the internal temperature is very high.

When nephritis is present as a complication, prolonged tepid (85 F) baths should be used, rather than cold procedures.

When the nervous system is depressed, the sudden impact of cold water and vigorous rubbing are invaluable to arouse the patient, to make him breathe better, and to take nourishment more readily. When the patient is restless and sleepless, a suitable cold wet pack is the best sedative that can be prescribed for the fever patient.

The following hydropathic procedures, arranged somewhat in order of increasing severity and antipyretic efficiency, may be needed to meet these various indications:

- (a) The cold head-compress
- (b) The antipyretic pack
- (c) Antipyretic ablution, or "sponging"
- (d) The sheet bath
- (e) The half bath
- (f) The full bath

(a) The cold head-compress is the single most universal hydropathic procedure in fever. It should, without exception or special order, accompany all antipyretic procedures. This compress is useful by itself to lessen febrile headache and to quiet the delirium of the fever patient. It is a wet towel, well wrung out of ice water, applied to the head like a turban. To be kept cold it must not be covered and it should be changed frequently (as often as it warms up) unless an ice-cap is included, which should be done in all severe cases.

It is a general principle in all hydrotherapy to keep the head cool and the feet warm. Hence, whenever there is a tendency for the feet to be cold, a properly protected hot water bag should be kept near them as a routine accompaniment of all other procedures.

(b) The most useful form of the antipyretic pack is the "trunk compress." It is mild enough to be used even for children and collapsed patients, and it is of value even in cases presenting very high temperatures in the intervals between the more radical procedures. The cold trunk compress for the child is a Turkish towel, for the adult a sheet folded so as to extend from the axilla to the hips and all round the body. It is wrung out of water at 60 F, covered with dry flannel (but not water proof), and changed every two hours for temperatures above 104 F. It is changed every hour for temperatures above 105 F and removed when the temperature falls below 103 F. In a fever with a long course, the temperature points may be set 1 degree

lower. If the trunk compress has not warmed up when changing is due, it should not be changed. If the skin is cold to start with, a mustard pack should be employed.

The anterior trunk-compress differs from the foregoing in that the wet cloth covers only the front and the sides to the posterior axillary lines, while the dry flannel covering extends round the patient. It is to be preferred because less disturbing when the patient is very sick and frequent changing is necessary. When changing is due, the flannel covering is opened and the fresh compress slipped in place.

For children and very sensitive patients the graduated trunk compress may be ordered. The first application may be at a neutral temperature (90 F) to avoid shock and fright, and the temperature of subsequent compresses should be reduced progressively by 5 degrees F each time until the desired result has been secured.

The cold wet pack is indicated in conditions of febrile restlessness and sleeplessness. It includes the patient's arms and shoulders as well as the legs down to the knees, the sheet being placed in such a way that wet sheet is between adjoining skin surfaces at all points. The sheet, having been lightly wrung out of water at about 60 F is placed on a dry woolen blanket and both are put underneath the patient so that the wet sheet is next to him. The patient then raises his arms above his head and half of the sheet is drawn across his body and tucked alongside the trunk and between the legs. Then the patient brings the arms down to his side and the other half of the sheet is brought around the body, covering the arms and shoulders and the rest of the body, its border being tucked in along the opposite side. Finally the woolen blanket is brought together in such a way as to make snug closure, most especially about neck and shoulders, and tucked under the feet so as to keep "air from getting at the wet." If a patient is chilly, additional covering may be used. Should the patient go to sleep in the pack, he is not disturbed. Otherwise the pack might be changed after it has thoroughly warmed up, possibly in an hour or two.

The "mustard pack" is a modification of the wet pack, consisting of the use of hot (105 F) water to which mustard (one heaping tablespoonful per liter) has been added for wetting the sheet (doubled up for this purpose). A dry blanket surrounds the wet sheet, particularly snug closure being made about the neck to keep the mustard fumes from affecting the patient's eyes. Every five minutes the skin is inspected for reaction, which first occurs on the surface on which the patient lies, and within fifteen to thirty minutes the application should be removed. This powerful appeal to redden the skin should be used whenever, in antipyretic hydrotherapy, redness cannot be brought to the skin by other means. A suitable ablution should be used as a finishing procedure to free the skin from the adhering mustard particles.

(c) Antipyretic ablution ("sponging") is the simplest and most commonly employed, but also mildest, measure. It may fail to make an impression on high or stubborn temperatures. It is, nevertheless, a useful preliminary to more powerful procedures, serving as a test of the patient's reactive capacity. The mattress is protected by water-proof material (oil cloth or mackintosh) covered with a blanket and a linen sheet that have been placed underneath the patient. After the head-compress has been applied and the patient's face

has been bathed with cold water, such water (at about 60 F) is freely thrown on the arms down to the elbow, the trunk both front and back, and the lower extremities down to the knees. A crumpled piece of gauze or the hollow of the hand may be used for carrying the water, which is dashed on the skin with one hand while the other hand carries out a continual chafing movement until the treated part warms up. Then another portion of the body is attended to and this is continued until all parts have been treated, special attention being given to the back, which is the hottest as well as the best reacting part of the fever patient's body. The surface is gone over in this manner two or three times until the temperature has been reduced, but never below 101 F, as it may sink further subsequently. The procedure should be ended earlier when it is found that the skin does not warm up readily under the rubbing. As finishing treatment, the patient is not dried at all if he is vigorous but merely rolled onto a dry sheet, the wet bed coverings being simultaneously withdrawn. If he is less vigorous, he is gently dried by wiping off excess of fluid but leaving the surface somewhat moist. If the patient is very sensitive, small portions of the body at a time are treated, dried, and covered immediately. If sedation is aimed at, the procedure might be finished by means of a general wet pack to keep the temperature from going up too rapidly and to lessen the number of spongings required. Trunk compresses may also be used for this purpose.

"Hot sponging," at 105 F, of portions of the body at a time followed by a warm (100 F) alcohol rub may give satisfactory results as an initial procedure for very nervous patients, especially children. The temperature of the water and of the alcohol may be progressively lowered at subsequent treatments, as judgment and experience indicate.

(d) The sheet bath is intermediate in potency between the ablution and the tub bath, for which it serves as a valuable substitute when a suitable tub is not available. It should be resorted to when the "sponge" is inadequate to reduce excessive febrile temperature satisfactorily. With the bed prepared as directed for "ablution," a sheet partly wrung out of water, ranging in temperature from 80 down to 50 F according to indications, is placed underneath the patient and wrapped about him so that no two body surfaces are in opposition without wet sheet between them. Then the sheet is chafed until it warms up, whereupon cold water (60 F) is dashed on by means of a cup and the sheet is again briskly rubbed and patted until "reaction" takes place, as indicated by warming up of the sheet. Then this process is repeated on another part of the body, and the entire surface (arms and legs excepted) is gone over and over again until the sheet does not warm up as readily as it did, until the patient shivers, or until the temperature has been reduced to 101 F. The procedure may be finished as discussed under "ablution."

The "ice rub" is the sheet bath modified by using a lump of ice, partly wrapped in cheese-cloth and passed over the surface with one hand while the other strokes and pats the part just treated with the ice for not more than fifteen seconds in any one place. It adds severity and efficiency to the sheet rub.

"Cold sprinkling" may often be successfully employed instead of a tub bath, when a tub is not available. In the emergencies of "heat stroke" it should be carried out wherever the patient with hyperpyrexia is found

and even before he is transported to the hospital, where recurrence of the high temperature may call for its renewed use. Sprinkling may be carried out in bed by raising the head of the bed about 1 foot from the floor and placing a rubber sheet (covered with a linen or cotton one) under the patient in such a way as to provide for drainage into a tub or pail. To keep the mattress from sagging, three boards the width of the bed may be placed under it. The sprinkling can should have a rather large rose nozzle and should be held 2 or 3 feet above the patient. A sprinkling hose attached to a hydrant may be employed, but of course excessive force of water impact should be avoided. Constant active friction must be kept up throughout the procedure. The sprinkling should be stopped from time to time to permit "reaction" to take place, and when this finally does not occur as readily as it did before or when the temperature has been reduced to 101 F, one of the finishing procedures is employed.

(e) The half bath is given in a tub containing water that reaches to the navel when the patient is sitting. While "tubbing" is always more or less troublesome for helpless adult patients, it is so easily carried out for small children that for these it should be the antipyretic procedure of choice, whenever the trunk pack proves inadequate.

Half baths may be prescribed as follows: "Neutral half bath (at 95 F) for five minutes with constant friction. Finish by cool affusion (at 75 F), followed by gentle drying."

For a more vigorous effect one might prescribe "Cool half bath (at 75 F) for ten minutes with friction. Finish by cold affusion (60 F) to neck, back and chest. Dry lightly."

In febrile collapse, when the skin is pale and cool and the pulse rapid, one might prescribe "Hot half bath (at 105 F) for five minutes, until skin reddens. Finish with brief sprinkling (from sprinkling can) of nape of neck with cool water (at 75 F). Rub dry."

Still more powerful a stimulant to the skin is the "mustard bath." Powdered mustard (one tablespoonful to the gallon) is mixed with a little water to form a thick paste and this is folded in a towel in such a way as to form a bag, which is hung in a hot (105 F), warm (100 F) or neutral (95 F) half bath for five or ten minutes, until the bath is sufficiently impregnated with oil of mustard. To protect the patient's nose and eyes a sheet may be thrown over the tub. The patient is bathed until the skin reddens.

(f) The full bath is one that reaches to the bather's chin. It must always be given with friction. "Rubbing is the keynote to successful tubbing." Two types may be recognized: the graduated bath and the full cold bath.

The graduated bath ("von Ziemssen bath") is given in a tub one third full with water at 90 F and accompanied by constant rubbing until the skin reddens. Then bucketfuls of cold water are added, so as not to impinge directly on the patient, until the temperature is lowered to 75 or even 70 F in the course of half an hour. It may be finished with a cold (60 F) affusion to the back of the head.

The full cold bath ("Brand bath"), the most powerful hydropathic procedure, has made a special reputation for itself in the prevention and treatment of the "typhoid" state (not only of that which occurs in typhoid). It is much more stimulating than the von Ziemssen bath. One might prescribe it at first as

follows "A full bath at 85 F with constant rubbing (abdomen excepted in typhoid) for five minutes with cold (60 F) affusions to head and back of neck for last two minutes followed by light drying"

If after such initial baths the temperature continues to rise and is not kept within bounds by these given every four to six hours, the temperature of the bath water is lowered to 75 F and the duration increased up to ten minutes, provided the patient reacts adequately. The feebler the patient, the briefer must be the duration of the bath, which makes the stimulating effect greatly overshadow the temperature reducing action.

#### "ELIMINATION"

Perhaps the least objectionable routine medication in fever—if routine medication there must be—is the administration of a diuretic. While it is extremely doubtful that the fever-producing toxins are sufficiently diffusible to be flushed out of the system by way of the urine, it is probably of advantage to the kidneys to secrete urine of lesser rather than of higher concentration. It might possibly lessen the danger of nephritis as a complication. The old fashioned "fever mixtures" handed down with such reverence for tradition by one generation of clinicians to another are nothing more or less than diuretics. It remains to be shown—though the possibility is not denied—that they are superior in value to simple and single agents. Of the various diuretics, the one that might be preferred is Sodium Citrate (prescription 1), which is a veritable fever "polychrest," being diuretic, expectorant, and in limit

#### PREScription 1—Sodium Citrate

R Sodium citrate	30 00 Gm
Water	30 00 cc
Strawberry syrup	to make 120 00 cc
Mix Label Teaspoonful in glassful of water or fruit juice every two hours	

doses also laxative. Furthermore, it is an indirect alkali, i. e., increases the alkali reserve of the system without neutralizing gastric juice, and it well may be that by antagonizing febrile acidosis it improves systemic functions in general and possibly thus even favors antimicrobial resistance. To secure these effects one must push it up to the limit of tolerance, which is usually set by either the stomach or the bowel. To minimize the production of nausea and possibly vomiting, each dose should be given in a glassful of fluid, preferably fruit juice such as lemonade, orangeade or grapeade. When it causes nausea in spite of this dilution or if it produces diarrhea, its dose needs to be lessened. It is believed to decrease the coagulability of the blood, possibly by inactivating calcium, which may also be the reason why its use is occasionally followed by urticaria.

#### RELIEF OF DISTRESS

The medicinal antipyretics, more appropriately termed "fever narcotics," differ fundamentally from antipyretic hydrotherapy in that they depress metabolism while lowering febrile temperature. As this depression may also mean a lessening of resistance, they should not be employed merely for the purpose of temperature reduction. They are useful, however, for the relief of the discomforts of fever such as headache and general aching restlessness, sleeplessness, and impairment of digestion especially because such comfort can generally be secured from doses inadequate to reduce the body temperature markedly or to produce untoward results, such as excessive sweating or collapse. They should be

given merely as required for the relief of these symptoms, which are usually most marked at the beginning of fever, and should be discontinued as soon as these symptoms are no longer complained of.

It is of advantage to distinguish between three groups (a) quinine, (b) salicylates and (c) pyrazol-paramidophenol compounds.

(a) Aside from its specific value in malaria (q v), quinine lowers temperature by depressing metabolism, slows the pulse, relieves neuralgic pains, and quiets the nervous system. By these effects it may favor a good night's sleep in a fever patient who might otherwise be restless and sleepless, and it might be given at bed time for this purpose, 0.3 Gm capsules of Quinine Hydrochloride every hour for two or three doses, administration to be discontinued if the ears ring. For children, Quinine Ethylcarbonate (euquinine, prescription 2) is preferable.

#### PREScription 2—Quinine Ethylcarbonate

R Quinine ethylcarbonate	5 00 Gm
Aromatic syrup of eriodictyon	60 00 cc
Mix Label Shake the bottle and give teaspoonful at bedtime (For child 5 years old)	

(b) While in rheumatic fever (q v) salicylate has a special value and is pushed to the limit of tolerance, preferably in the form of sodium salicylate, Acetylsalicylic Acid may be employed in 0.3 Gm capsules for its analgesic value every two to four hours (as required) to relieve aches and pains, provided it does not cause excessive sweating.

(c) The cheapest and most active of the pyrazol-paramidophenol compounds, acetanilid, is best given in unit doses of 0.1 Gm capsules or tablets every hour or two until the patient is relieved. The administration is at once discontinued if pallor, cyanosis, faintness or tachycardia is produced. Acetphenetidin, in twice the dose, produces almost identical effects, excepting that these are slower in appearing and there is less tendency to cyanosis and faintness. It is best given in 0.3 Gm capsules or tablets at intervals of two to four hours as required. Amidopyrine, given in doses of 0.3 Gm tablets every two to four hours, has of late been suspected of the possibility of producing neutropenia. Hence, while patients are given this drug, the leukocyte count should be particularly studied. A periodic leukocyte count should be routine, however, in every fever patient, no matter how treated. Antipyrine is the one of this group that is sufficiently soluble to be administered in liquid dosage form, hence it is suitable for children (prescription 3). As it may be irritative to the stomach when given in solid dosage form, it should always be prescribed in solution. It is the only one of these that may be given as an enema if oral administration is impossible.

#### PREScription 3—Antipyrine

R Antipyrine	2 00 Gm
Syrup of raspberry	60 00 cc
Mix Label Teaspoonful every two hours as required (For child 3 years old)	

#### COMBATING PYREXIAL COLLAPSE

At the bedside of every fever patient stands the dread specter of collapse, commonly due to primary paresis of the blood vessels, especially of the capillaries. It is probably the result of direct poisoning of the histiocytic system by bacteria deposited there from the blood stream. All the previously discussed regimen includes a recognition of this danger of collapse and aims, as far as possible, at its prevention.

For appropriate therapy it is necessary to distinguish between primary myocardial failure and vascular collapse. In certain diseases, e g, diphtheria, myocardial involvement is the anatomic substratum of the sudden appearance of often rapidly fatal heart failure, which may occur even when convalescence seems assured. For the treatment of this condition, see Acute Myocarditis. In vascular collapse, the first territory to be attacked is the splanchnic, so that with blood accumulating there the skin becomes pale and cool, and the heart, attempting to keep the gaping blood ways filled, beats faster and faster. At first there is but little lowering of the blood pressure. When the vasomotor center fails, probably owing to insufficient circulation in it, a vicious circle develops and the blood pressure becomes greatly depressed—a serious second stage sets in, which is characterized by paresis of the skin capillaries with development of cyanosis of the lips and nose, finger tips and toes. When finally the heart itself fails from malnutrition and overwork (a second vicious circle) and the pulse becomes irregular—sometimes, at intervals only—the condition is desperate indeed.

If the foregoing characterization of events is correct, the physician must aim at forestalling the development of the vicious circles referred to. On the other hand, circulation stimulants should not be employed too early or unnecessarily, because some, such as digitalis, may by cumulative action produce intoxication and also because they may call out a display of stored energy when it is not required and fail to do so when this is needed.

**Digitalis**—The employment of digitalis when the pulse commences to become rapid is based on the relative slowness with which—unless it is used in heroic dosage or by injection—its effects are secured. One may start from 1 to 2 cc of the Tincture of Digitalis or with 0.1 to 0.2 Gm of Digitalis Leaves (in capsules) given every eight hours. It should not be continued in these doses for more than three or four days unless the patient is under close observation. In either case the dose should be lessened or stopped as soon as improvement is secured, as evidenced by better quality of heart sounds, better pulse quality (the rate may not be lessened), improvement in blood pressure, or when the pulse becomes slow or irregular, or if nausea and vomiting ensue. In view of the efficiency of the official preparations made by reliable manufacturers, it is inexcusable to prescribe higher priced proprietaries on the basis merely of high pressure salesmanship, nor is there any justification for prescribing the injectable preparations that are required in an emergency, unless such an emergency really exists, and then only during the emergency, to be followed by oral digitalis administration. For injection purposes, if digitalis has not been given previously, strophanthin may be injected intravenously very slowly, in doses of from 0.25 to 0.5 mg, preferably in 10 cc of 25 per cent solution of dextrose once daily every third day or, if given daily, for not more than three days. Digitalis administration should have been discontinued for two or three days before the injection of strophanthin.

**Camphor**—Because of the possibility that it may have a favorable stimulant action on the peripheral circulation with a quieting effect on the central nervous system, camphorated oil (20 per cent) injected intramuscularly in large doses (5 cc) is recommended once or twice a day to establish a depot from which this

agent of otherwise but fleeting action may gradually be absorbed. It is probably contraindicated when there is evidence of myocardial failure.

**Caffeine Sodibenzoate**—Five-tenths gram of caffeine sodibenzoate in 2 cc of ampule water given intramuscularly may be special value in cases in which there is also cerebral depression. Its effect is rather fleeting and it may have to be repeated several times daily. Cupfuls of "black" coffee may be given as a retention enema.

**Strychnine Nitrate**—In doses of 2 mg hypodermically given every two hours or even every hour, until the pulse is slowed or the reflexes are exaggerated, strychnine nitrate is too well established clinically to be discarded as an available stimulant on the basis of negative experiments on healthy animals. It may possibly act indirectly by stimulating suprarenal secretion.

**Solution of Epinephrine**—In doses of 0.5 to 0.75 cc, Solution of Epinephrine, preferably administered in dextrose phleboclysis, may be of telling but unfortunately transient effect. If there is myocardial weakness, one must be careful not to overwhelm the heart with a large bulk of injected solution, and it is at such a time that the epinephrine might with advantage be added to the hypertonic (25 per cent) dextrose solution injected slowly in quantities of from 10 to 20 cc.

**Atropine Sulphate**—From 0.5 to 1 mg of Atropine Sulphate, given hypodermically every two to four hours up to the pharmacologic effect (dryness of the mouth, dilated pupils), is especially indicated in collapse with "leaky" skin such as may occur during a crisis in pneumonia. After its use, improvement in the circulation must be judged by the increased determination of the blood to the skin rather than by slowing of the pulse, for atropine in liberal doses may accelerate the heart beat while improving circulatory conditions.

**Volatile Agents**—So-called diffusible stimulants, such as alcoholic liquor and Aromatic Spirit of Ammonia, have been discussed under alcohol. Amyl nitrite inhalation (0.3 cc glass capsules) may be tried in an effort to bring blood to the skin, especially in an attempt to check a chill.

**Mechanical Means**—Methods of improving the distribution of the blood, such as elevation of the foot of the bed in vasomotor collapse or propping the patient up in bed in myocardial failure, should not be neglected in desperate cases. In sudden vascular collapse, centripetal massage of the limbs followed by snug bandaging from the feet to the hips and a tight abdominal binder may help tide a patient over a critical condition.

The very number of means employed in stimulating a failing circulation indicates lack of a really satisfactory remedy. The patient should not be pled with them indiscriminately but should rather receive them in accordance with one's knowledge of their pharmacologic action and special indications and with critical evaluation of results, whether good or bad.

#### TREATMENT OF CONVALESCENCE

When the temperature has become normal, the question of how rapidly the patient may get up and out of bed and back to work becomes important. As a general proposition, the convalescent patient feels better than he really is. It is a good rule to continue absolute bed treatment for as many days of normal temperature as there have been days of abnormal temperature. This rest period must be greatly extended in diseases with a tendency to the development of chronicity or of con-

plications Thus, in acute rheumatism or in acute nephritis, weeks rather than days of bed treatment are required, in acute endocarditis or in tuberculosis, months rather than weeks When there is a definite tendency to serious complications during convalescence, as the myocardial failure of diphtheria or the nephritis of scarlet fever, the patient should be kept in bed for several weeks, even though he seems perfectly well

The presence of even a slight rise in temperature day after day may be one of the troubles of a convalescent It usually indicates a focus of infection or a complication that requires being sedulously searched for Sometimes constipation or the premature assumption of a general diet is the cause of the rise in temperature, so that its occurrence indicates revision of diet and possibly the administration of a laxative

In cases in which subfebrile temperature continues and in which the blood picture and all other tests for complicating infection are negative, the possibility of a residual excessive irritability of the heat-regulating center may be tested for by the administration of amidopyrine (0.3 Gm tablets every hour for not more than three doses), the effect of each dose being observed to forestall collapse The temperature may not only go down but stay down In this manner prolonged sanatorium treatment has sometimes been shown to be unnecessary

Scarcely less important than the temperature record in the management of convalescence is the pulse rate As long as this goes up at the least exertion or after the slightest excitement, rest rather than exercise is indicated

When the patient seems ready to be permitted to get up, the transition should be made the more gradually the more severe, prolonged or exhausting the disease has been After a prolonged sickness, when the leg muscles have become very much weakened, the patient may be encouraged to exercise the legs by punching with them a pillow laid at the foot of the bed Sitting up in bed with the aid of a back rest is generally the first order for a patient after long continued recumbency At first this may have to be but for a short time, as the patient may get tired very easily Next the patient is helped to get into a chair at the side of the bed and sit there for say five minutes, possibly twice a day, morning and evening, while the bed is being made The time spent out of bed may usually be doubled daily, and, after a few days, the patient may be assisted in taking walking exercises During all first exertions of convalescents, one must be on the lookout for dizziness, faintness or even fainting This is especially apt to occur when a patient rises quickly for defecation or urination Stair climbing and walking in the open are all items of exercise to be carefully planned and graded Before a convalescent is exposed to the inclemencies of weather, he should be subjected to a graded course of hygienic hardening procedures No greater error can be made than to send a feeble convalescent on a trip to the distant South before he is well able to get around and take care of himself Then a vacation of weeks or months before returning to work is of great advantage

**Diet**—A convalescent usually develops a good appetite, and thus should be appeased with discretion The mistake is often made at this time to feed the patient beyond his digestive capacity, and the resulting indiges-

tion may give rise to feeding problems that may delay recovery of strength

**Tonic**—The anemia usually present in the convalescent indicates the administration of iron, which may be given in the form of Pills of Ferrous Carbonate (Blaud's pills), of which one or two may be taken three times daily after meals For children, the Saccharated Ferrous Carbonate may be prescribed in the form of 0.3 Gm powders or of tablets, to be chewed like candy If a liquid administration form is desired, Iron and Ammonium Citrate (prescription 4) meets all requirements For infants and small children the Syrup of Ferrous Iodide, given in drop doses in the feedings, usually furnishes adequate iron intake

#### PRESCRIPTION 4—Iron and Ammonium Citrate

℞ Iron and ammonium citrate 10.00 Gm  
Syrup of orange to make 120.00 cc  
Mix Label Teaspoonful in water three times daily after meals

#### PRESCRIPTION 5—Arsenic and Mass of Ferrous Carbonate

℞ Arsenic trioxide 0.06 Gm  
Strychnine sulphate 0.06 Gm  
Mass of ferrous carbonate 10.00 Gm  
Mix and divide into thirty pills Label One three times a day after meals

If the patient's appetite is slow in returning, the addition of arsenic to the mass of ferrous carbonate may be of advantage Whether or not strychnine favors the return of "pep," the fact is that it is frequently added to "tonic" medication If used, it should be prescribed in pill form (prescription 5) rather than in the form of such an abominably tasting liquid as the Elixir of Iron, Quinine and Strychnine

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

PAUL NICHOLAS LEECH Secretary

#### DEXTROSE (See New and Nonofficial Remedies, 1934, p 270)

The following dosage forms have been accepted

**Dextrose Solution 25 Gm 50 cc** A solution marketed in bottles and containing anhydrous dextrose 25 Gm in sufficient distilled water to make 50 cc

Prepared by the United States Standard Products Co Woodworth Wis

**Dextrose Solution 50 Gm 100 cc** A solution marketed in bottles and containing anhydrous dextrose 50 Gm in sufficient distilled water to make 100 cc

Prepared by the United States Standard Products Co Woodworth, Wis

#### TRIETHANOLAMINE-CRUDE (See New and Nonofficial Remedies, 1934, p 203)

**Triethanolamine-Carbide and Carbon Chemicals Corporation**—A brand of triethanolamine-crude (N N R)

Manufactured by the Carbide and Carbon Chemicals Corporation New York

#### TUBERCULIN-KOCH (See New and Nonofficial Remedies 1934, p 384)

Parke, Davis & Company, Detroit

**Tuberculin for the Mantoux Test**—A filtrate from bouillon cultures of both human and bovine strains of *Bacterium tuberculosis* containing 50 per cent of glycerin as a preservative Marketed in packages of two 10 cc vials one containing 0.01 cc tuberculin old and the other 10 cc of diluent

## ANTI-HORMONES

In 1921 Harvey Cushing<sup>1</sup> delivered a notable address before the Association for the Study of Internal Secretions, in which he took severely to task those who would apply to therapeutics the contributions then but recently made in endocrinology. The association, he warned, "must discountenance the exploitation of the few discoveries which have already been made by those who recklessly under full sail plow through a fog bank of therapeutics, their horns tooting." Thirteen years ago, active glandular extracts were few and most endocrine therapy was "polyglandular." Today, however, there are many pure or nearly pure extracts the effects of which are fairly well known and more or less controllable. It was thought that these preparations must surely at last provide effective means for the treatment of disease, and they have been extensively (even incautiously) employed for this purpose. Thus, modern therapists have not heeded the excellent advice of Dr. Cushing, they have indeed been led "to embark glandward ho!" Little did they realize, however, how jealously nature guards our body economy, for, as Collip and his associates<sup>2</sup> have just shown, there are "antihormones."

Potent endocrine preparations are often administered to patients and frequently the desired effects may be attained, but, curiously, an individual here and there, who should promptly be cured by this extract or that, not only fails to improve but occasionally even becomes worse. The dose is increased without effect, the preparation is then condemned or the patient given up as hopelessly refractory. Now comes an answer to those who have been reckless enough to believe in the endocrine millennium. The organism does not so readily accept assaults on its glandular equilibrium—not without a struggle—it produces antihormones.

Zondek<sup>3</sup> and subsequently other investigators have pointed out that injection into animals of anterior

pituitary-like principle from urine of pregnancy results first in increase in the size of the ovaries, followed by regression to normal dimensions despite continued administration. Injection of this principle into rats over a sufficiently long time may lead to diminution in the size of the ovaries even to less than normal.<sup>4</sup> This loss of sensitivity appears to be specific for the factor administered, as ovaries refractory to the anterior pituitary-like principle will still respond to preparations of the anterior pituitary itself.<sup>4</sup> The reverse also has been demonstrated.<sup>5</sup> Hertz and Hisaw,<sup>6</sup> using an ovarian follicle stimulating fraction from the anterior pituitary,<sup>7</sup> noted that during repeated injection of their extract into young rabbits the ovaries, which at first were enlarged about fivefold, gradually regressed to their original size. Further injection of the extract failed to elicit any ovarian response, the glands became refractory and even after two or three months did not undergo normal development. The injection of sub-threshold doses, insufficient to induce a detectable morphologic change in the ovaries, also caused the latter in most cases to become resistant to the subsequent injection of large and usually effective amounts of the follicle stimulating factor.

Other examples of such phenomena are known. It has been claimed that the continuous administration of an extract of the corpus luteum cannot maintain the endometrium of the rabbit in a stage of progestational proliferation for more than about seventeen days.<sup>8</sup> Thereafter, despite further injections, the mucosa atrophies. Such reactions are not limited to the gonads and accessory reproductive organs. Loeb and Friedman<sup>9</sup> for instance, reported that guinea-pigs rapidly lose their sensitivity to the thyroid stimulating factor of the hypophysis, and recently, through the efforts of Collip and his associates,<sup>2</sup> other instances have come to light. In fact, these investigators have established the presence of specific antagonistic substances in the blood stream, which Collip has designated by the name already mentioned.

On injection of the thyrotropic principle of the pituitary into animals, hyperplasia of the thyroid gland occurs and the metabolic rate rises sharply. However, continued injections of the extract do not maintain this condition, the metabolic rate returns to normal in two or three weeks and may even go below normal. The animals fail to respond subsequently to doses even as large as eight times the previously effective dose.

Transplantation of thyroid tissue from normal rats into refractory animals also is ineffective in raising the metabolic rate. Serum obtained from rats thus rendered refractory, when administered to other rats, effectually prevented the effect of the thyrotropic factor,<sup>10</sup> while normal rat serum or normal horse serum had no such effect. But rats the blood of which contained the inhibitory factor still responded to desiccated thyroid with a rise in metabolic rate.

Anderson and Collip<sup>11</sup> have succeeded in preparing highly potent antithyrotropic extracts of the serum of a horse injected for some time with thyrotropic factor. Similarly, a serum that inhibits the effects of the growth principle of the pituitary,<sup>2</sup> and another that prevents the gonadotropic activity of the hypophyseal-like fraction from the urine of pregnancy, have been obtained.<sup>12</sup> Evidence has also been adduced for the existence of yet other antihormones.<sup>2</sup>

Not only are these observations of great fundamental significance, they emphasize further the necessity for the utmost caution in the clinical use of endocrine products. Repeatedly, warnings against the indiscriminate application to therapeutics of our still fragmentary knowledge of glandular physiology have been issued by those who, like Cushing, have provided the foundation for the present exceedingly active work in this subject. Only a year ago the Council on Pharmacy and Chemistry<sup>13</sup> pointed out the possible dangers of the unconsidered administration of such active agents in the field of gynecology. The investigations discussed here provide emphatic substantiation of this point of view.

#### VITAMIN D IN BLOOD AND IN MILK

Irradiated milk and the milk from cows given feed that has been enriched in vitamin D through added viosterol, either as such or as irradiated yeast, rank peculiarly high in relative antirachitic potency when compared to other commonly used sources of this accessory food factor. This observation, naturally, has raised many questions. Granted the therapeutic excellence of these foods, is it advisable or practicable to insist that all market milk should be augmented in vitamin D potency?<sup>1</sup> What change occurs in the milk which renders it so much more efficacious in the treatment of rickets than an equivalent number of units of vitamin D in other forms?<sup>2</sup> What precautions must be taken in fitting the subject to this new form

of dietotherapy?<sup>3</sup> And one might reasonably inquire into the workings of the physiologic mechanism whereby the lactating mammal transports and possibly transforms the vitamin D of the food into that of the milk.

A recent study by Light, Wilson and Frey<sup>4</sup> bears on the vitamin D content of the blood and milk of cows fed irradiated yeast. The animals under investigation were part of a herd that was being regularly fed in this way for the commercial production of "yeast milk." It was observed that after one dose of the yeast the rate of disappearance of vitamin D from the plasma was more rapid in the early hours after feeding, when the concentration was high, than later. Furthermore, as might be expected, there was an apparent dependence of level of the antirachitic factor in the milk on that in the plasma. Examined more promptly after the irradiated yeast had been fed, the plasma showed a distinct rise in content of vitamin D in from one to two hours. Taking into account the quantity fed and the amount appearing in the blood, it was calculated that "practically 100 per cent of the vitamin D fed appears in the blood." In contrast is the relatively small proportion of the ingested antirachitic factor appearing in the milk, some 2 to 3 per cent.<sup>5</sup>

The studies of the fate of vitamin D in the cow doubtless have a significant bearing on the behavior of this substance in man; they indicate that a large part of this food factor ingested cannot be accounted for by bio-assays of feces, milk or tissues. There seems to be no doubt that it enters into metabolism in some manner, which in turn may be influenced by its own chemical make-up or that of the associated compounds.

#### SPIROCHETAL JAUNDICE IN SEWER WORKERS

Spirochetal jaundice (Weil's disease) has received occasional notice in the American literature for a number of years. It seems to be one of those conditions fated to play an ever larger part in medicine and public health. To date, however, it has been of sufficient rarity, at least as far as the diagnosis is concerned in this country, to be still in the realm of case reports. During the last ten years, according to Schuffner,<sup>1</sup> 452 cases have occurred in Holland with forty-six deaths. Since the chief vector appears to be the rat, it would be surprising if no further cases should appear in this country.

Additional interest in the possibilities of Weil's disease is aroused by the recent report of Fairley<sup>2</sup>. The case noted by him was in a man of 25 who for the

greater part of two years had been unemployed but who twenty-two days before the onset of his illness had joined a gang of workmen engaged in repairing a sewer in London. From a clinical point of view his case was typical of fatal Weil's disease. It presented the usual sudden onset with rigor, extreme prostration, muscular tenderness and severe jaundice on the fifth day. Later multiple hemorrhages, herpes and renal involvement with albuminuria, oliguria and anuria occurred, terminating with death on the eleventh day. It was subsequently reported that two guinea-pigs inoculated with blood collected from the patient on the seventh day of the disease had sickened, and necropsy revealed jaundice and visceral hemorrhages, the characteristic postmortem features of Weil's disease. Typical leptospiras were demonstrated by dark field illumination in emulsion of liver pulp from one animal and in the heart blood of both. Serum collected from the patient on the tenth day of illness and sent to Professor Schuffner in Holland gave a strongly positive agglutination reaction with the typical Weil strain leptospira.

This unusual experience led Fairley to investigate the histories of a number of other sewer workers in London. In one fatal case, the history of which was somewhat similar to the first, the coroner had returned an "open verdict—toxic hepatitis—but there was no definite evidence to show how or by what means the toxic condition had arisen." In eight other sewer workers a more or less detailed history of severe illness associated with jaundice was obtained. Blood serum was collected from three individuals at varying times after their illness. The agglutination reactions, which were performed by Professor Schuffner, were strongly positive in seven of the eight cases, varying from 1 in 100 to 1 in 1,000 when living or formalized cultures of the classic "Weil" strain, *Leptospira icterohaemorrhagiae*, were employed.

The mode of infection was of particular interest. The series of cases reported comprised sewer laborers engaged in repairing or rebuilding old sewers. Among other duties their work consisted in chiseling away and removing the old brickwork in a section of sewer under repair, and during this process the skin of their hands was often traumatized. The inner surfaces of bricks lining the sewer are covered with a slimy deposit, and contact with sewer water was inevitable. Rats, which are recognized as the principal carriers of the leptospira of Weil's disease, are naturally numerous in many sewers. It is recognized, moreover, that leptospira can exist in slime for undetermined periods of time.<sup>3</sup>

In this country, up to 1933, eight cases of leptospiral jaundice had been reported. Ball<sup>4</sup> reported two more cases in that year, in neither of which was it possible to determine the exact source of infection, though both

individuals had apparently been in close contact with rat infested buildings. At least one of the American cases was in a sewer worker.<sup>5</sup>

Two points are worthy of emphasis in this connection. Diagnostic keenness in considering the possible leptospiral etiology of some obscure cases of jaundice is certainly desirable. The industrial hazard inherent in occupations involving close contact with rats or their moist excreta must be considered potentially important. In view of the widespread exposure to rat infested buildings, exaggerated by the depression, it is surprising that no more extensive infection with the leptospira of Weil's disease has been reported. As Fairley pointed out, however, since jaundice develops in only about 50 per cent of cases of leptospirosis, a serologic as well as clinical investigation of those exposed, e g, sewer workers, should be undertaken.

## Current Comment

### MUTUAL ANTAGONISM OF BACTERIAL VARIANTS

The test tube incompatibility of certain bacterial species has long been known. It has been generally assumed that different strains, types or variants of the same bacterial species can be grown together in perfect symbiosis. Now test tube antagonism has been demonstrated between different phases (R and S) of the same bacterial species. About two years ago Dr Ettinger-Tulczynska<sup>1</sup> of the Robert Koch Institute, Berlin, began to suspect such interphasic antagonism. He found, for example, that mice simultaneously inoculated with two types of pneumococci almost invariably yielded a pure culture of but one type at necropsy. In less than 10 per cent of the cases could both types be isolated from blood cultures or from necropsy material. A similar complete suppression of the minority type or phase was afterward demonstrated in artificial mediums. This interphasic antagonism was afterward shown to be due to an unknown integrating factor,<sup>2</sup> conceivably a type-stabilizing or type-transforming bacterial hormone.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH, ETC.)

### ARKANSAS

**Another Impostor**—Using the name Louis Giraud, a man has been presenting letters of recommendation at various hospitals throughout the country in an effort to obtain financial aid or employment as a chemist. Rev Joseph H Schumacher, chaplain of St Vincent's Infirmary, Little Rock, writes that his name was fraudulently used on a letter presented at Mercy Hospital, Pittsburgh, by Giraud. When the man visited St Vincent's, authorities there were warned that the man was a fraud. Giraud claims that he was falsely sentenced to twenty years on a penal farm in Arkansas for forging signatures.

### CALIFORNIA

**Maternal Mortality Reduced**—There were 364 maternal deaths in California in 1933 as compared with 448 during 1932, giving respective rates of 48 and 57 per thousand births. Among white women the rate was 43, Mexican 65, Japanese 61, Negroes 11 and Indians 133. The rate was higher in rural districts than in urban centers. The state board of health pointed out that about 70 per cent of all confinements in the state take place in maternity homes and hospitals.

**Personal**—Dr Nolton N Ashley has been appointed health officer of Oakland, succeeding Dr Arthur Hieronymus, who has resigned after several years' service, effective June 11. Dr Stanley R Parkinson, Marysville, has succeeded Dr James H Barr as health officer of Yuba County. Dr Denver D Roos has been appointed health officer of Corona, following the retirement of Dr William S Davis. Dr Clelia D Mosher, emeritus professor of personal hygiene, Stanford University, received the honorary degree of doctor of laws from Mills College, June 11, at its seventy-seventh annual commencement.

### CONNECTICUT

**Psychiatric Society Formed**—The Connecticut Society of Psychiatry was organized at a meeting at the Connecticut State Hospital, Middletown, May 10, to foster the study of nervous and mental disorders, to improve standards of care for patients, and to advocate and foster preventive psychiatry. Dr Allen R Diefendorf, New Haven, was elected president.

### DISTRICT OF COLUMBIA

**Ophthalmic Society Organized**—The Washington Ophthalmological Society was organized in May. Membership is also open to physicians in Maryland, Virginia, West Virginia and North Carolina. Officers are Drs William Thornwall Davis, chairman, Le Roy W Hyde, vice chairman, and James N Grcear Jr, secretary.

**Society News**—Dr Joseph G Pasternack of the National Institute of Health was installed as president of the Washington Pathological Society, June 2. Dr George A Alden, pathologist, U S Naval Medical School, was chosen vice president, and Dr Virgil H Cornell, curator of the Army Medical Museum, was reelected secretary. At the opening meeting of the society this fall a symposium on lymphatic tumors will be presented.

### FLORIDA

**Society News**—At a meeting of the Pasco-Hernando-Citrus Counties Medical Society in Inverness, June 15, Dr Henry C Dozier, Ocala, gave a paper on "Cancer Problems—The Responsibility of the Larynx" and Dr Robert D Ferguson, Ocala, one on "Aneurysm." Dr Ralph E Russell, Ocala, discussed glaucoma. Drs Charles D Cleghorn and John W Snyder addressed the Dade County Medical Society, August 3, Miami, on "Skin Tumors" and "Gritti-Stokes Amputation for Gangrene of the Leg," respectively.

### GEORGIA

**Society News**—Speakers before the Telfair County Medical Society in Lumber City, July 10 were Drs Wade H Born and Frank R Mann, both of McRae, on "Affections of the Anus and Rectum" and "Tonsillar Infection and Its Importance to the General Practitioner," respectively. Dr Loren

Gary Jr, Shellman, discussed typhoid before the Randolph County Medical Society in Cuthbert, July 5. Dr Theodore Toepel, Atlanta, read a paper on arthritis before the Walker County Medical Society at Rossville, July 6. At a meeting of the Jackson-Barrow Counties Medical Society in Jefferson, July 2, Dr Samuel A Boland, Jefferson, read a paper on treatment of rheumatism in children. The Fulton County Medical Society was addressed, August 2, by Dr Stacy C Howell, Atlanta, on "The Action of Epinephrine on the Normal Human Eye." Dr Lewis M Gaines, Atlanta, gave a clinical talk on "Heart Symptoms without Heart Disease." Dr William Perrin Nicholson Jr, Atlanta, addressed the Tenth District Medical Society in Washington, August 8, on "Breast Lesions."

### ILLINOIS

**Personal**—A public celebration was held at Cissna Park, July 15, in honor of Dr William R Roberts, who has practiced thirty-five years in the community.

**Society News**—Dr William J Carter, Mattoon, discussed stomach disorders, among other speakers before the Coles-Cumberland Medical Association at Neoga, July 19. Dr Felix W Sokolowski addressed the Madison County Medical Society in Alton, August 3, on increase of mental disorders and importance of mental hygiene.

**Epidemic Encephalitis at Highland**—An outbreak of nine cases of epidemic encephalitis with four deaths in Highland was reported by the state board of health, August 8. The disease appears to be of the same type that prevailed in St Louis during the summer of 1933. Twenty-five cases occurred in Highland and Madison County during last year's epidemic. All the patients except one were more than 50 years old.

### Chicago

**Research on Asthma and Hay Fever**—The Research and Educational Hospital of the University of Illinois College of Medicine, 1819 West Polk Street, is carrying on experiments to determine whether electrical changes in the air during storms are related to attacks of pollen asthma. Ten women were invited to participate in the research, which began August 15 and will continue until September 31.

**Dr David Made Chairman of Surgical Department**—Dr Vernon C David, since 1929 clinical professor of surgery, Rush Medical College, has been appointed chairman of the department, succeeding Dr Arthur Dean Bevan, who has held the position since 1902. Dr David graduated from Rush in 1907 and has been connected with the school since 1910. His first appointment was as assistant in surgery. Dr Bevan will continue with his work at Presbyterian Hospital and at Rush as Nicholas Senn professor of surgery. He began his association with the school in 1887 as professor of anatomy. He is also an alumnus of Rush, having graduated in 1883.

### INDIANA

**Personal**—Dr George W Willison, Dale, has received the Raydn medal, which is awarded annually by Dr Marcus Raydn, Evansville, to the member of the senior class of Indiana University School of Medicine making the highest average in the four years course for the degree of doctor of medicine. Dr Willison graduated in medicine at the recent commencement. Dr Henry F Beckman, clinical professor of obstetrics, has been made head of the department of obstetrics of Indiana University School of Medicine, Indianapolis.

**The Credit Department**—Since the establishment of the Medical and Dental Business Bureau, Indianapolis, March 1, 6,602 accounts for collection have been referred by 156 physicians, and 1,251 accounts by sixty-six dentists. The bureau is now serving in delinquent collections a total of 222 physicians and dentists on 7,853 accounts. A total of \$4,767.80 has been collected from March 1 to July 21. About 400 of the accounts filed for collection owe from two to eight physicians and dentists each. The bureau was established for members of the medical and dental societies of Indianapolis.

**Sanitation Programs**—An appropriation of \$2,000 for cleaning and repairing drainage ditches in Marion County, including the sanitation of a sewage ditch at New Bethel, where a typhoid outbreak recently occurred was voted by the county council, July 14. Judge Schlosser of the superior court recently ordered the council to appropriate money for cleaning the New Bethel system. June 20, eleven cases of typhoid were reported in New Bethel, which has a population of about 350 (THE JOURNAL, July 21, p 194). A sanitation program has also been initiated in Shelby County as a project of the Emergency Relief Administration.

## IOWA

**Society News**—Dr Merle J McGrane, New Hampton, was elected president of the Cedar Valley Medical Society at its meeting at Clear Lake in July, and Dr Ray A Fox, Charles City, secretary—Dr Paul J Hanzlik, San Francisco, addressed the Linn County Medical Society, July 26, at Cedar Rapids, on "Advancement in Pharmacology and Treatment"

**Annual District Meeting**—The Iowa and Illinois Central District Medical Association held its annual meeting in Davenport, July 27, with the following speakers

Dr Harry L Alexander, St Louis Allergy  
Dr Herbert W Rathic Waverly Value of Theophylline in Treatment of Arteriosclerotic Heart Disease  
Dr Owen H Wangersteen Minneapolis Diagnostic and Therapeutic Considerations in Management of Acute Abdominal Lesions  
Dr Clifford J Barborka Chicago Diet and Disease

Dr John C Souders, Rock Island, Ill., was elected president and Dr James Dunn, Davenport, secretary

## KANSAS

**Reelect Board Members**—Dr John F Hassig, Kansas City, was reelected president of the Kansas Board of Registration and Examination at its annual meeting in Topeka, June 19, and Dr Charles H Ewing, Larned, was reelected secretary Dr Edwin C Morgan, Clay Center, was appointed a member of the board for four years

## MARYLAND

**Changes at Johns Hopkins**—Dr Ludwig Edelstein, formerly of the University of Berlin, has been appointed associate in the history of medicine at Johns Hopkins University School of Medicine It was also announced that Dr Edward H Hume New York, will give the Noguchi lecture and Dr Pasteur Vallery-Radot, Paris, the Thayer lecture during the coming year

**Health Survey in Montgomery County**—One thousand families in Montgomery County will be interviewed on health problems in a survey to be undertaken at once by the U S Public Health Service in cooperation with the local health department, it was announced, July 27 The survey is part of a general study being made in three counties of the country, Montgomery County, Forsyth, N C, and Fairfax County, Va Data on illness, medical, nursing or dental care during the last year will be gathered in addition to other information on general health problems It is hoped that the study will determine what services are performed by county health departments, which persons receive these services and what effect the services appear to have on existing health problems All information concerning individuals will be kept confidential

## MICHIGAN

**Dr Warnshuis Goes to California**—Dr Frederick C Warnshuis, Grand Rapids, for many years speaker of the House of Delegates of the American Medical Association and secretary of the Michigan State Medical Society, will go to California, October 1, to become secretary and director of public relations of the California State Medical Association Dr Warnshuis, a native of Iowa, has been secretary of the Michigan State Medical Society for about twenty-one years

**Annual Report of Children's Fund**—During the year ended April 30, 1934, a total of \$452,395.11 was expended by the Children's Fund of Michigan to carry on its work in emergency relief, child health, child guidance research and dependency Because of the depression some programs were eliminated and others were curtailed The greatest expenditures continued to be in the field of child health During this fifth year of the fund's existence, about 280,000 children received some form of service The feeding of malnourished children in the Detroit area was carried on as a supplemental program to that of the social service committee of the Detroit school system Eight dental clinics were maintained in school buildings, with an extraction clinic at Grace Hospital for serious cases and a tenth clinic at the Boys Club of Detroit Thirty-six counties and two urban areas were served by the all year dental program, and twenty additional counties received the benefit of the ten weeks summer program which was given over entirely to corrective processes as heretofore Eleven counties in the state were served by two traveling ophthalmologists, who examined children's eyes and prescribed glasses when necessary The fund purchases glasses when parents are not able to afford them At the beginning of the year all grants for research not done directly in the fund's laboratory were discontinued with the exception of the study of childhood

tuberculosis carried on through the St Vincent de Paul Society by Dr John A Johnston of Henry Ford Hospital The fund did not reduce its appropriation to the Michigan Children's Aid Society, which is used in helping dependent children in the less prosperous sections of northern Michigan, where the population is scattered The children taken care of under this grant are supported wholly by the fund during the whole year Green Pastures, summer camp for Negro children at Little Picasant Lake, Jackson County, was also operated to its full capacity by the Urban League for Negroes Grants included one to a special committee of the Wayne County Medical Society that helps indigent persons receive medical treatment from practicing physicians

## MINNESOTA

**Society News**—Dr Charles W Mayo, Rochester, addressed the Mower County Medical Society at Austin, recently, on abdominal surgery—Dr James S Reynolds, Minneapolis, was recently elected president of the Minnesota Academy of Ophthalmology and Otolaryngology, Drs Hendrie W Grant, St Paul, and Frank N Knapp, Duluth, vice presidents, and Dr Walter E Camp, Minneapolis, secretary

**Bell Lectureship Established**—The Hennepin County Tuberculosis Society has established the Dr John W Bell Lectureship in tuberculosis in the Hennepin County Medical Society Under this lectureship, an authority on tuberculosis will address members of the society at the December meeting, which this year will be December 3 Dr Bell, who died in 1933, was a member of the House of Delegates of the American Medical Association from 1919 to 1923 He was emeritus professor of medicine and at one time professor of physical diagnosis and clinical medicine, University of Minnesota Medical School Dr Bell also served as president of the Minnesota State Medical Association, Hennepin County Medical Society and the Minnesota Academy of Medicine and was a member of the state senate from 1891 to 1895

**President Roosevelt Presents Award to Drs William and Charles Mayo**—The President of the United States made the presentation address at a ceremony in Rochester, August 8, when the National American Legion Citation was conferred on Drs William James and Charles Horace Mayo "for distinguished service to our sick and disabled comrades and to humanity in general" Introductory addresses were made by Clarence L Fischer commander of William T McCoy Post, through which the citation was presented, Gregory P Gentling, chairman of the citation committee and Michael F Murray, St Cloud, state commander of the Legion Edward A Hayes, Decatur, Ill., national commander of the Legion, made the presentation of citations to the Doctors Mayo, to which Dr Charles H Mayo responded Then followed the unveiling of a bronze plaque, which the President presented President Roosevelt paid tribute to the physicians and to modern medicine, to which he said those concerned with government and economics are under obligation in two important respects Medicine has shown how it is possible for human beings to control and improve conditions under which they live, he declared from medicine also have been learned lessons in ethics of human relationships—"how devotion to the public good unselfish service, never ending consideration of human needs are in themselves conquering forces" The plaque, designed by Harold H Crawford, Rochester architect, bears profile portraits of the recipients in bas relief modeled by Mrs George Trenholm, daughter of Dr Charles H Mayo Charles Brioschi, St Paul was the sculptor It bears the inscription "Gift of the William T McCoy post, presented by Franklin Delano Roosevelt, president of the United States, at Rochester, Minn., August 8, 1934" It was estimated that 75,000 persons were present Before the ceremony the President laid a wreath at the foot of a statue of Dr William Worrell Mayo father of the honored physicians On the evening of August 7, a public testimonial meeting was held at Soldiers Field, attended by about 8,000 persons Speakers at this meeting were Gov Floyd B Olson, St Paul Frank B Kellogg, St Paul, former Secretary of State and now judge of the Permanent Court of International Justice Fred W Sargent, Chicago, president of the Chicago and Northwestern Railway Dr Walter L Bierring, Des Moines, Iowa President of the American Medical Association, Dr Morris Fishbein, Chicago, editor of THE JOURNAL, Dr William D Haggard, Nashville, Tenn., president of the American College of Surgeons Gerald V Barron national Legion committeeman from Minnesota and Earl Cliff, vice chairman of the national Legion rehabilitation committee Dr William J Mayo responded to these tributes At a dinner at the Kahler Hotel preceding this meeting Dr Francis J Savage, St Paul, president of the Minnesota State Medical Association, welcomed more than 300 distinguished guests

## NEW JERSEY

**Personal**—Col John H McCullough, Trenton, state surgeon of the national guard, was recently awarded a distinguished service medal by order of the governor, in recognition of his forty-two years' service in the infantry and medical corps of the national guard, according to *Military Surgeon*. Dr McCullough was also in federal service during the World War.

## NEW YORK

**Society News**—The Medical Society of the County of Erie has recently removed its offices from the Museum of Science to room 1810, Hotel Statler, Buffalo.—Dr Herman E. Wangler, Syracuse, addressed the Suffolk County Medical Society, July 25, at Southold, on medical treatment of gall-bladder disease.

**Heart Disease in High School Students**—The cardiac subcommittee of the Medical Society of the County of Monroe under the chairmanship of Dr Rufus B. Cram recently published results of a four year survey of heart disease among students in the high schools of Rochester. Of 425 adolescents examined, 197 were found to have organic heart disease, 62 potential disease and 110 possible disease. At the time of examination, 142 were not under medical supervision. Sixty-seven were recorded as not eligible for gymnasium or competitive athletics and 147 eligible for gymnasium only. Vocational guidance was recommended for 176. In 1931 this was found to be 38 per cent in 1932, 32 per cent. In 1933 the figure was 30 per cent and in 1934 it was 27 per cent, in these two years seventy-five reexaminations were made, which are not included in the estimates. Eighteen physicians contributed their services in making the examinations.

## New York City

**Society News**—Dr Howard Lilienthal was elected president of the New York Physicians' Art Club at the annual meeting in May, and Dr Louis C. Schroeder secretary. The club held its annual exhibit in April at the New York Academy of Medicine (THE JOURNAL May 19, page 1688).

**Seventh Graduate Fortnight**—The seventh annual graduate fortnight of the New York Academy of Medicine will be held October 22 to November 2, on diseases of the gastrointestinal tract. Clinics will be held each afternoon in various hospitals and there will be extensive scientific exhibits at the academy with demonstrations at regular intervals by many of the exhibitors. At evening sessions at the academy the following speakers will be presented:

Drs Harlow Brooks, Walton Martin and Robert E. Pound: General Principles Involved in Diagnosis of Gastrointestinal Diseases.  
Dr Andrew C. Ivy, Chicago: Applied Physiology of the Innervation of the Gastrointestinal Tract.  
Dr Henry James Spencer: Constipation.  
Dr John L. Kantor: Diarrhea.  
Dr Carl Eggers: Diseases of the Esophagus.  
Dr Burrill B. Crohn: Functional and Nervous Diseases of the Stomach.  
Dr John Douglas: Diseases of the Pancreas.  
Drs Williams McKim Marriott, St. Louis; Rustin McIntosh and Charles E. Farr: Disorders of the Gastrointestinal Tract in Children.  
Dr Charles F. Tenney: So Called Chronic Appendicitis.  
Dr John E. Jennings: Acute Appendicitis.  
Dr Charles Gordon Heyd: Peritonitis.  
Drs Arthur F. Chace and Eugene H. Pool: Peptic Ulcer.  
Dr Fordyce B. St. John: Carcinoma of the Stomach.  
Dr Reuben Ottenberg: Jaundice.  
Drs William W. Herrick and Allen O. Whipple: Gallbladder and Biliary Passages.  
Dr John F. Erdmann: Tumors of the Colon.  
Dr Harvey B. Stone: Baltimore Diseases of the Anus and Rectum Including Tumors.  
Drs Walter A. Bistado, Thomas T. Mackie and Francis W. O'Connor: Colitis.  
Dr Arthur M. Wright: Intestinal Obstruction.  
Dr Dean Lewis: Baltimore Diverticulitis.

**Epidemiologic Study of Trichinosis**—Within the past five years 166 cases of trichinosis have been reported to the New York City Department of Health. In all but sixteen there was a history of having eaten pork and twenty-nine persons admitted having eaten it raw. Seven stated that they had not eaten pork and in nine cases no information was available. Women were more frequently attacked than men, a fact accounted for by the closer contact of women with the preparation of food. The majority of the cases were in persons between 20 and 35 years of age and cases were numerous in the German and Italian populations of the city. The source of the food supply was traced to the wholesalers and it was found that in more than two thirds of the cases the food had been purchased from local butchers or eaten in local restaurants whose products had been passed by the inspectors of the U. S. Department of Agriculture. The government agencies have repeatedly called attention to the fact that inspection is

not a criterion of freedom from trichinae, the report points out. In view of the impossibility of subjecting every animal slaughtered to microscopic inspection, the government limits its regulations to the pork products that are customarily eaten raw and only for those products insists on adequate cooking or refrigeration for twenty days. Dry salting, pickling and smoking, which have been shown to be sufficient to destroy trichinae, are permitted. It is believed that many cases are not recognized or are not reported. Physicians are requested therefore, to report all suspicious cases of gastro-intestinal disease following ingestion of pork or pork products. In addition the problem of educating persons to eat pork only when thoroughly cooked cannot be emphasized too strongly, the report concluded.

## SOUTH CAROLINA

**Society News**—Drs Charles R. F. Baker and Robert B. Bultman, both of Sumter, addressed the Sumter County Medical Society, June 7, on fractures and early diagnosis of pregnancy, respectively.—Dr Edward A. Looper, Baltimore, addressed the Columbia Medical Society, Columbia, June 11, on "Diagnosis and Treatment of Diseases of the Larynx, Trachea and Bronchi."

## TENNESSEE

**Health Exhibit at Fair**—A health and medical exhibit has been planned for the Mid-South Fair in Memphis September 3-8, under the auspices of the Memphis and Shelby County Medical Society. The medical, dental, pharmaceutical and nursing departments of the University of Tennessee will have exhibits, and local physicians will prepare displays showing progress in prevention and treatment of various diseases. A special section will be devoted to food and dietetics. The Shelby County Tuberculosis Society will demonstrate its work.

**Graduate Courses in Nashville**—The Nashville Post-graduate Medical Association was recently chartered as a "nonprofitmaking organization for the purpose of giving to practitioners of medicine a brief review of medical and surgical subjects at the smallest cost of time and money" and the first series of courses was held June 25-29. Twenty-three physicians from towns of middle Tennessee attended the classes and clinic conducted by Nashville physicians. Dr Harrison H. Shoulders, Nashville, is president of the association. It is anticipated that the graduate course will be made an annual event.

**Health at Memphis**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended August 4 indicate that the highest death rate (187) appears for Memphis and the rate for the group of cities as a whole 99. The mortality rate for Memphis for the corresponding week of 1933 was 175 and for the group of cities, 106. The annual rate for eighty-six cities for the thirty-one weeks of 1934 was 119 as compared with 113 for the corresponding period of 1933. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

**Society News**—Physicians of Robertson, Montgomery, Cheatham, Stewart and Houston counties at a meeting at the Idaho Springs Hotel near Clarksville, July 17, organized the Black Patch Medical Society with Dr Maurice L. Hughes, Clarksville, as president and Drs William S. Rude, Ridgeway and Paul E. Wilson, Clarksville, as secretaries. Drs John M. Lee and James C. Overall, Nashville, among others, addressed the meeting on 'Feeding Infants with Summer Diarrhea' and 'Acute Respiratory Diseases,' respectively.—Drs Jewell M. Dorris, Memphis, and Guthrie Y. Graves, Bowling Green, Ky., addressed the Tri-County Medical Society (Carroll, Henry and Weakley counties) at McKenzie, July 10.—Dr Henry Hedden, Memphis, among others, addressed the Memphis and Shelby County Medical Society, Memphis, July 3, on costs of medical care.

## VIRGINIA

**State Board Members Reappointed**—All members of the state board of medical examiners were reappointed recently with the exception of Dr Alex. F. Robertson, Jr., Staunton, who represented the tenth congressional district. As the number of districts was recently reduced to nine by legislative enactment reappointment of Dr Robertson was precluded. Dr Philip W. Boyd, Winchester, is president of the board and Dr John W. Preston, Roanoke, secretary.

## WASHINGTON

**Society News**—Drs George H Anderson and Edward S Jennings, Spokane, addressed the Chelan County Medical Society, Wenatchee, June 7, on "Abdominal Symptoms of Cardiovascular Disease" and "Unusual Phases of Appendicitis," respectively—Three Seattle physicians addressed the Walla Walla Valley Medical Society, Walla Walla, June 14, as follows: Drs Edward D Hoedemaker, on "The Psychiatrist in Future Medicine," George W Swift, "The New Outlook for Medicine" and Donald V Trublood, "Importance of Early Diagnosis of Cancer"—Dr Charles E Watts, Seattle, among others, addressed the Yakima County Medical Society, Yakima, June 11, on cardiac disease.

## WEST VIRGINIA

**Society News**—Drs Frank S Johns and Marvin Pierce Rucker, Richmond, Va, addressed the Central West Virginia Medical Society, July 18, at Webster Springs, on "Treatment of Acute Appendicitis" and "Rupture of Membranes as a Means of Induction of Labor," respectively—Dr Moritz F Petersen, Charleston, addressed the Fayette County Medical Society, Oak Hill, July 10, on "Hypothyroidism in Infants"—Dr Athey R Lutz, Huntington, presented a paper on "Deformities Usually Encountered in the Crippled Child" before the Cabell County Medical Society, July 12—At a joint meeting of the Monongalia and Preston county medical societies in Hopemont, July 6, speakers were Drs George L Leslie, Howell, Mich, on "Collapse Therapy in the Treatment of Pulmonary Tuberculosis," and David Salkin, Hopemont, on "Intestinal Tuberculosis"

## GENERAL

**Changes in Status of Licensure**—The New York State Board of Medical Examiners reports the following revocations made at a meeting of the board of regents, June 22

Dr Malcolm Cameron Rose New York, license revoked following his conviction in federal court of violating the Harrison Narcotic Act, he was sentenced February 14 to serve three years in Northeastern Penitentiary, Lewisburg, Pa

Dr Maurice Minton New York license revoked on the charge of having performed an illegal operation

**The New Mexico Board of Medical Examiners reports**

The license of Dr Arthur H DeLong Gallup was revoked April 9, following his conviction on the charge of violating the Narcotic Act

**Study of Neoplastic Diseases**—The American Association for Study of Neoplastic Diseases will meet in Washington, D C, at the Mayflower Hotel, September 6-8. Seven sessions will be held, with chairmen as follows

Dr Joseph Colt Bloodgood, Baltimore Lantern Slide Demonstration of Microscopic Pathology

Dr Charles F Geschickter, Baltimore Microscopic Pathology

Dr Wright Clarkson Petersburg Va Symposium on Bone Tumors

Dr James F Kelly Omaha Nebr Ray Diagnosis of Neoplastic Diseases

Dr John Shelton Horsley Richmond Va Symposium on Neoplastic Diseases of the Gastrointestinal Tract

Dr Edwin A Merritt Washington D C Radiation Therapy in Neoplastic Diseases

Dr Max Cutler Chicago Symposium on Neoplastic Diseases of the Breast.

**National Recreation Congress**—The twentieth National Recreation Congress will be held in Washington, D C, October 1-5, sponsored by the National Recreation Association. There will be no papers. The congress will divide itself into discussion groups beginning Tuesday morning and continuing through the day and each morning thereafter. Wednesday, Thursday and Friday mornings at 11 o'clock the entire congress will come together to hear reports from these discussion groups. Wednesday and Thursday afternoons will be left free for special meetings. Friday afternoon will be devoted to special meetings. General meetings will be held each evening, with addresses by prominent speakers. Headquarters will be at the Wardman Park Hotel.

**News of Epidemics**—Four new cases were reported, August 11, in the epidemic of bacillary dysentery in Jersey City, N J. Eighty cases remained in Jersey City hospitals. Deaths of two children in Monmouth County from the infection were also reported, August 11—Twenty-two cases of typhoid in Blackhawk County, Iowa, recently were traced to contaminated milk. All the families involved bought milk from the same dairy—Eighty-two cases of typhoid occurred in an epidemic in Augusta, Maine, recently, all living along a single milk route. An examination of all food handlers in the city resulted in the removal of four carriers from food handling jobs, one was found to be employed on a dairy farm—Five persons have died among twenty-five cases of Rocky Mountain spotted fever in Maryland this year, the state board of health reported August 6

**Congress of Physical Therapy**—The thirteenth annual session of the American Congress of Physical Therapy will be held at the Bellevue Stratford Hotel in Philadelphia, September 10-13, under the presidency of Dr Albert F Tyler, Omaha. The William Benham Snow Memorial Lecture will be given the opening day by Drs Andre Halphen and J Auclair of the Hopital H de Rothschild, Paris, on "Pyrotherapy by Means of Thermogenic Physical Agents." In addition to the clinical conferences of the various sections there will be symposiums on gynecology and cancer Wednesday and Thursday, respectively. Participating in the general sessions will be, among others

Dr Morel Kahn chief of service, department of electro-radiology

Hopital de la Pitie Paris on Applications of Lapicques Currents

Dr Joseph C Doane Philadelphia Histamine Iontophoresis in the

Treatment of Vasospastic Conditions

Dr Jacob Gershon Cohen Philadelphia Roentgenologic Studies of the

Colon by Means of the Double Contrast Enema

Dr Leroy W Hubbard Warm Springs, Anterior Poliomyelitis (moving picture demonstration)

Dr Disraeli Kobak Chicago Radiotherapy in Medicine

Drs Charles J Suto and Michael S Burman New York Value of

Fluorescence in Medicine

James Houston Shrader Ph D Johns Hopkins School of Hygiene and

Public Health Baltimore The Fortification of Milk with Vitamin D

A joint meeting of the congress and the Philadelphia County Medical Society will be held Wednesday evening, September 12, with Dr Russell L Cecil, New York, as the speaker, on "The Modern Medical Approach to the Problem of Arthritis," and Dr Hugh H Young, Baltimore, "Malignant Tumors of the Bladder and Prostate"

## CANADA

**Society News**—The Canadian Public Health Association held its annual meeting in Montreal, June 11-13, among speakers were Drs Albert Grant Fleming, Montreal, on "The Relationship of Public Health to Medical Care" and Dr Antonio Bolduc, Montreal, "Amebic Dysentery Its Public Health Significance and Control"

**Hospital News**—It was recently reported that the Grenfell orphanage and school at Cartwright, Labrador, which served as a hospital for the region and for the northern fisheries, had been burned with the loss of one life. Erected four years ago, the institution was valued at \$100,000. Sir Wilfred and Lady Grenfell were at their summer home in Charlotte, Vt, when they received news of the fire.

**French-Speaking Physicians Meet in Quebec**—A congress of French-speaking physicians, a combined meeting of the Association of French-Speaking Physicians of North America and the French Congress of Medicine, will be held in Quebec, August 27-31. French physicians from France, Belgium and Switzerland will attend the congress and spend several weeks traveling in Canada and the United States. Subjects to be treated in symposiums include pancreatic syndromes, hypoglycemic states and pyrotherapy. Sessions will be held at the Chateau Frontenac and practical demonstrations will be given in various hospitals. Presidents of the joint congress are Drs Albert Paquet, Montreal, and Sergent, Paris. The general secretary is Dr Vaillancourt, Paris.

## FOREIGN

**British Medical Election**—Sir Richard R Stawell, Melbourne, Australia, was chosen president of the British Medical Association for 1935-1936 at the annual meeting at Bourne mouth in July. Dr Sydney Watson Smith, Bournemouth, was made president for the coming year. The annual meeting will be held in Melbourne next year.

**Society News**—The Manchester Medical Society, Manchester, England, will celebrate its hundredth anniversary in October. A commemorative meeting will be held October 3 with an exhibit of historical interest and a history of the society will be issued.—The ninth International Congress on Dermatology and Syphilology will be held at Budapest, Sept 15-21, 1935, under the presidency of Prof Ludwig Nekam. Budapest—An International Congress of Medicine as applied to sports will be held in Vittel, Vosges, France, September 2-4.

**Congress on Biologic Action of Radiation**—The first International Congress on Electro-Radio-Biology will be held at the Doges Palace, Venice, Italy, September 10-15. Senator Guglielmo Marconi and Count Giuseppe Volpi di Misurata, secretary of state, will preside at the opening session. Among Americans listed on the program are William D Coolidge, Ph D, and C P Haskins Schenectady, N Y. Arthur H Compton, Ph D, Chicago, Otto Glasser, Ph D, Cleveland, and Robert W Wood, Ph D, Baltimore. Applications of radiation to medicine and therapy will not be examined in this congress.

### LONDON

(From Our Regular Correspondent)

July 21, 1934

#### Eradication of Ancylostomiasis from South African Mines

Gold was discovered on the Rand in 1886 and crowds rushed there. At first all drilling was done into dry rock, an enormous amount of fine dust was raised and the miners developed silicosis in five years and on an average died from it after working ten years. About seventeen years ago a new method of drilling was introduced, in which water is automatically pumped through the drill, the mines became wet and after two years hookworm disease (ancylostomiasis) appeared. At first it was mild but after seven years it threatened the industry. As the native miners are recruited from districts where the disease is endemic, its introduction was inevitable. The ova of the worm are passed in the feces and under suitable conditions of temperature, moisture and darkness are hatched in about two days. The larvae bore through the human skin and so man is infected. The requisite conditions of temperature and moisture existed in the Rand mines for the flourishing of the larvae, and the latrines were misused or not used at all by the native miners. Feces were left on the floor, to be trodden on by later comers. The lowest levels of the mines (from 3,000 to 7,000 feet down), where the temperature is highest, became heavily infested with the larvae and the higher levels infested to less degree.

In the *Irish Journal of Medical Science*, Dr. J. H. Hodgman has described how by a simple method the infestation was overcome. In February 1927 the Transvaal Mine Medical Officers Association made a number of recommendations for prophylaxis. All East Coast natives were to take a dose of 3 cc of carbon tetrachloride prior to their distribution in the mines and again a week later. The underground latrines were to be so constructed as to prevent pollution of the mine, and a coal-tar disinfectant was to be applied daily. Unfortunately the carbon tetrachloride treatment was not without risk, and five natives succumbed to poisoning. The prophylactic campaign was carried out energetically, but it was found that the infected soil was sterilized only to a depth of about one-fourth inch, beneath which the larvae thrive. Moreover, disinfectants when so concentrated as to kill larvae were harmful to the miners' hands and boots, and the expense was enormous. It was then noticed that hookworm infestation in India was not so severe in the coastal villages as in centers farther away, and Dr. Fischer accidentally discovered that strong solution of common salt was fatal to the larvae. Salt disinfection of the mines was then carried out. Once a week the floors and walls of the latrines for at least a height of two feet, as well as the perches or seats were scrubbed with a 20 per cent solution. A layer of coarse salt was strewn over the floor in the vicinity of the latrines. A layer an inch thick was placed at the bottom of the underground buckets when put in position in the latrines, and a similar layer when they were removed. The layer of salt about the latrines took a week to melt. Eight days after this treatment the floor which previously swarmed with larvae, was found to be sterile. It was also found that salt solution had excellent and quick powers of penetration. Since October 1927 salt disinfection has been extensively used. All the shafts, slopes and drives of the mines are salted. The mines are now clear of hookworm ova and larvae and it is impossible for any miner to become infected.

After this success underground attention was turned to the miners in the hospitals suffering from ancylostomiasis. Thymol, 30 grams (2 Gm.), was given and the dose was repeated

after two hours and an ounce of magnesium sulphate was administered an hour later. The thymol proved a fairly good vermifuge but the natives objected to the repeated treatments and hated being purged. Carbon tetrachloride, 3 cc., was usually curative after two treatments but had to be abandoned because of the danger. Like chloroform, it is apt to damage the liver. Oil of chenopodium has the advantage that no preliminary starvation or purge is necessary, but it is nauseating and is usually given in capsules, 14 cc. divided into three doses, which were taken at intervals of an hour. Complete cure resulted from four treatments and there were no fatalities. In 100 cases the maximum dose of 3 cc. was given and in seven neurotoxic symptoms (dizziness, headache, deafness and depressed action of the heart) were produced. It was then decided to experiment with a combination of the two drugs. They mix freely and the mixture does not increase the toxic effect of either. On the other hand, the results show that on the worms their effects are supplementary. Carbon tetrachloride, 2 cc., and oil of chenopodium, 1 cc., were put into one gelatin capsule and given. There is no need for starvation or purgation. One capsule is taken on an empty stomach, and liquid or semisolid food can be allowed at once. The patients leave the hospital the same evening and may resume work on the following day. This treatment has been carried out for two years in thousands of cases. Most of the patients were cured by one treatment, some by two, and a third was occasionally necessary. A lapse of ten days was allowed between the treatments. Ancylostomiasis is now rare in the mines.

#### Tropical Macrocytic Anemia

At the London Association of the Medical Women's Federation, Dr. Lucy Wills described her work on tropical macrocytic anemia during the last five years. In 1928 tropical macrocytic anemia was described under the name of "the pernicious anemia of pregnancy," which was a serious cause of maternal and fetal mortality in the large cities of India. The blood picture resembles that of pernicious anemia but there are the following differences from idiopathic pernicious anemia: (1) earlier age incidence and association with pregnancy, (2) absence of remissions except after delivery, (3) free gastric hydrochloric acid in normal amounts in the majority of cases, (4) absence of a raised indirect van den Bergh reaction or increase in urinary urobilin, (5) absence of nervous involvement, (6) slight differences in the blood picture—less poikilocytosis, less polychromasia and higher leukocyte counts. The cases are febrile frequently, but no evidence can be obtained of infection or toxemia. The disease responds to liver treatment, which suggests a nutritional origin. It was later found to occur in men and nonpregnant women. It is evidently a deficiency disease and its prevalence in pregnancy can be explained by the increased demands on the maternal organism. A deplorable multiple deficiency in diet was found among the hospital classes of Bombay, particularly want of vitamins A and C. Macrocytic anemia was produced in rats and monkeys on this diet. The addition of marmite to the diet proved curative. At this time Castle's work on the intrinsic and extrinsic factors of blood formation appeared. As the tropical cases apparently presented normal gastric secretion, it was inferred that it was the extrinsic factor which was deficient.

#### The Medical Service of the Air Force

In *THE JOURNAL*, June 23, p. 2124, revised conditions for the medical services of the army and navy were reported. A reduction in the medical establishment of the air force is to be brought about by abrogating at all stations other than the college and flying training schools the rule that a medical officer must stand by whenever flying is in progress. The result will be that it will be necessary to carry only one medical officer at flying stations. Arrangements will be made for a

local physician to be summoned in the absence of a medical officer. After five years' service all permanent officers will be given the opportunity of taking a course of specialist study and the promotion to squadron leader of officers who obtain a specialist qualification will be accelerated. The ages of promotion will be reduced and the proportion of officers enabled to reach higher ranks will be increased. The pay of squadron leaders will be increased by \$125 a day. The gratuities payable to short service officers will be \$2,000 on transfer to the reserve after three years' service and \$5,000 after five years.

#### International Memorial to Florence Nightingale

The Florence Nightingale International Foundation was inaugurated in London under the chairmanship of Sir Arthur Stanley, who read to delegates of nursing societies from all over the world a telegram from the queen. She was glad to hear that the memorial would take an educational form, as this would have commended itself to Miss Nightingale, who had the training of nurses so much at heart. Telegrams of congratulation from the Japanese and Chinese Red Cross societies were read. The chairman explained that the business was to elect officers and committees of management for the foundation. The purpose of the foundation was to provide postgraduate nursing education on a permanent basis for a selected group of fully trained nurses, drawn from those in the forefront in all countries. The foundation would be governed by a grand council comprising representatives of the International Council of Nurses, the League of Red Cross Societies and the Nightingale memorial committees, formed or to be formed in each country. Eighteen such committees had already been constituted. The foundation started its work at once and took over the international courses for nurses conducted in London until last year by a committee including representatives of the International Council of Nurses and the League of Red Cross Societies. In handing over its task the committee reported that arrangements for continuing the courses during 1934 and 1935 had already been made, and twenty nurses with suitable qualifications had been nominated to participate. Officials were elected from the countries of the world. The American ones were Miss Adelaide Mary Nutting, emeritus professor in Columbia University, honorary president, Mrs Draper, American Red Cross Society, Miss Ann Goodrich, Yale University School of Nursing, and Miss Jean Gunn, superintendent of nurses, Toronto General Hospital, vice presidents.

#### Shortage of Water from Prolonged Drought

Prolonged shortage of rain has caused considerable concern as to water supplies. The minister of health has issued a circular to local authorities urging them to formulate plans immediately for meeting any serious shortage in their area. Health officers should make sure of the purity of any new sources and also of existing sources where the supply is low. Where necessary the water should be chlorinated or otherwise purified. Where water for domestic purposes is conveyed in carts, tanks or other vessels, care should be taken that they are clean. If sufficient rain does not fall before September, a serious shortage may be expected and detailed plans should be prepared at once.

#### Sir Frederick Hopkins Honored

Sir Frederick Gowland Hopkins, who has been the leader of biochemistry for a quarter of a century and is now president of the Royal Society, has been awarded the Albert medal of the Royal Society of Arts. He has been professor of biochemistry in the University of Cambridge since 1914. He received the Nobel prize in 1929, the royal medal of the Royal Society in 1918 and the Copley medal in 1926. His most important work has been done on vitamins. Previous Albert

medalists include such eminent men as Faraday, Kelvin, Joule, Helmholtz, Edison, Lister, Bunsen, Crookes, Rayleigh, Marconi, J. J. Thomson, Lodge and Lord Rutherford.

#### A New Antistreptococcus Serum

Professor Vincent, who in 1929 announced an antistreptococcus serum, has not ceased working to perfect it and to increase its potency. He recently presented it before the Academy of Medicine in its new form, with which one is able to secure recoveries in such grave cases as septicemia and streptococcal suppurative meningitis. The bacteriologic diagnosis must be exact, for the serum has no action on infections caused by the enterococcus, *Streptococcus mucosus*, *Streptococcus putridus* or *Micrococcus foetidus*. In some hospitals the serum is injected prophylactically into suspected patients (fractures of the cranium, confinements and in otorhinolaryngologic cases). In the septicemias the serotherapy should be used as long as signs of infection persist. After defervescence (usually on the sixth to the ninth day), when the patient should be recovering, one injects 30 cc and then 20 cc for four or five days. It is useless to combine with the serum other vaccinal or chemical medication. In his statistics, Vincent has entered not only all the deaths observed in patients correctly treated but also the deaths occurring in patients who died from complications not dependent on the streptococcus, or who received an inadequate dose of serum or were treated in the last phase of the disease. Recoveries could be effected, particularly in puerperal septicemia, in patients treated on the fifteenth to the twentieth day, but recoveries are then much more infrequent than in cases treated early. The septicemias treated (all of cutaneous, buccal, nasopharyngeal, otitic, genital or pulmonary origin) numbered 136, the number of recoveries was 111 (81.62 per cent), and the number of deaths was 25 (18.38 per cent). A large proportion of the patients who recovered had serious complications: pneumonia, purulent pleurisy, suppurative arthritis, meningitis, meningomyelitis, cerebral abscess, phlegmon of the orbit, general peritonitis, hemorrhagic nephritis, and the like. In eight cases of septicemia complicated with endocarditis, recovery occurred in seven. In malignant endocarditis lenta the serum is ineffective. The number of cases of meningitis treated with a serum was eight, with seven recoveries. The interest in Vincent's research lies in the fact that, without pretending to be effective in all cases, his new serum has increased the number of types of streptococcal general infection amenable to serotherapy. The results are dependent on the promptness of treatment and on whether the doses of serum employed are adequate.

#### The Cancer Institute at the Faculté de Médecine

Eight years ago there was created at the Hôpital de Villejuif an anticancer center just outside the city of Paris. This soon became the most important center in France for the study of cancer, its creation having been promoted by Mr Paul Strauss, who was then minister of public health. The director of this center as Mr Gustave Roussy, who became later professor of pathologic anatomy and just recently dean of the Faculté de médecine de Paris. The Villejuif center has now become a school for the study of cancer. The latest development is the addition of a hospital to serve exclusively for the treatment of cancer patients. The hospital was recently opened by the president of the republic. The buildings of the hospital and the research institute erected on the grounds of the Hôpital de Villejuif occupy 15,000 square meters. The hospital is a three story building, with a hall 280 meters in length, which affords a survey of all the wards. The illumination is excellent,

and aeration is assured by filtered air from the basement. A cool or warm temperature, as may be desired is maintained by machines, regulated by merely pressing a button. On the ground floor are the consultation rooms and the radioscopic, radiographic and radiotherapeutic rooms. There are four rooms for radiotherapeutics, under the direction of Dr. Belot, three of them being equipped with apparatus with a capacity of from 200,000 to 300,000 volts. A fourth apparatus is being constructed with a potential of 750,000 volts. The control chamber of the electric current is isolated from the treatment wards and is connected with these by a microphone for the reception of instructions from the physician and by an apparatus that registers automatically under the eyes of the physician the amount of voltage employed. The department of curietherapy, which occupies the second floor, is under the direction of Madame Laborde. The institute has 7 Gm. of radium, 2 Gm. of which is distributed in numerous tubes and needles. Five grams is enclosed in a bomb for intensive treatment. A mechanical device raises the container readily above the patient lying in bed. When not in use, the container and needles are enclosed in a large cylinder, which an elevator carries 35 meters underground. The radium room is lined with lead 12 mm. thick. The nursing personnel is subjected regularly to blood examinations and is changed every year. The third floor is occupied by the surgical department of Prof. Pierre Duval. The roentgenograms are illumined in a recess of the wall under the eye of the operator. The hospital contains 150 beds. There are rooms with twelve, eight and four beds, and individual rooms for patients who can afford the expense.

### The Admission of Physicians to Panel Practice

The federal ministry of labor issued new regulations concerning the admission of physicians to practice in the *kranken-kassen*, which went into effect July 1. Any physician seeking admission to such practice must be enrolled in the federal medical register, and registration may be denied if the physician is not a German citizen in full standing. The medical registers kept in the various districts are combined in the federal medical register, which is kept by the *Kassenärztliche Vereinigung* of Germany and which furnishes information to the committees on admission, the ministries and the leagues of the *kranken-kassen*. The federal register is always open to inspection on demand. One physician is admitted for every 600 members of the *kranken-kassen*. The relation of the number of panel physicians to the number of insured members is established by the committee on admission at the beginning of a calendar quarter and is announced publicly. If in a given district the number of panel physicians exceeds 1,600, only one physician shall be admitted for every three retiring panel physicians until this proportion is reestablished. In districts in which the proportion of panel physicians to the total membership is especially high, the number of physicians newly admitted may be still further restricted or, if need be, all admissions may cease for a time. Exceptions to these rules may be made if the filling of the post of the retiring panel physician is necessary for the assurance of the medical treatment of the members previously attended by him. A panel physician is admitted to practice in one of the towns or in one of the town districts for which the physician made application. In towns in which the specialists among the panel physicians amount to more than 40 per cent of the total only practicing physicians may be admitted to panel practice. If in a town in which no panel physician has settled the admission is needed admissions for other towns of the same district may be refused until a physician is admitted for the town in which an emer-

gency exists. If furthermore the admission of a physician in a rural district would seriously affect the living of a previously admitted physician, it may be ordered that within certain limits no physician shall be admitted until further notice. The purpose of these regulations is to enforce in general a definite relation between the number of physicians and the number of insured.

A requirement for admission is at least two years of preparation for panel practice in the *kranken-kassen*. During this period the physician must serve three months as assistant or *locum tenens* of a panel physician with a general practice carried on chiefly in a rural district. On completion of the two years a candidate may submit for consideration his experience as an assistant in hospitals up to twenty-one months, practice in camps designated by the federal leader of the panel physicians up to twelve months, as assistant of panel physicians up to nine months, and practical medical experience in medico-scientific institutes up to six months. A recognized course of postgraduate study also receives consideration. Experience as an assistant or voluntary physician is not counted if the physician attended to his own practice at the same time. In the case of physicians gravely injured during the war or of physicians who during the struggles associated with national movements were severely injured, some leniency may be shown, although they must have had at least one year of practical medical experience.

Excluded from admission are physicians of non-Aryan origin and physicians whose spouse is of non-Aryan origin. If one grandparent of a physician is a non-Aryan, he may be rejected. In case of doubt, a special certificate of the official expert must be secured. Thus, in the future, no more non-Aryan physicians will be admitted as panel physicians. If non-Aryan physicians admitted before the enactment of this regulation make it evident that they are not always ready to support firmly the national-socialistic state, they may, following a specific condemnation by the federal leader (Dr. Wagner) of the *Kassenärztliche Vereinigung*, be permanently excluded.

Married women physicians will be excluded unless their participation in panel practice appears needed for the protection of the family. Physicians who as officials have a regular income of at least 400 marks (\$150) a month will not ordinarily be admitted to panel practice. In the case of married physicians, 500 marks (\$190) is the limit with 50 marks (\$19) added for each child in the physician's immediate family. In the matter of admissions, special preference will be shown physicians with grave war injuries, physicians who served in the war, exiled physicians and married physicians (with exact consideration of the number of children). Special training courses for newly admitted panel physicians are being organized.

These new regulations constitute the most important part of the laws pertaining to panel physicians.

### Tuberculosis in Children

Dr. Ulrich, director of a large sanatorium for lung patients, stated in a recent address before the Berlin Medical Society that mortality from tuberculosis in children has declined during the past ten years. He was, however, unable to state with certainty whether the morbidity had changed for the better. If any suspicion attaches to children, the tuberculin test must be applied. In children of school age the tuberculin test is not so reliable, in fact during the school age period the diagnosis is much more difficult because the clinical picture has fewer manifest symptoms. At this time certain slight symptoms should be heeded, even though they may seem unimportant—such as fatigue, loss of appetite or a strange psychic behavior. The school physician can perform valuable service in the early recognition of the disease. Children in the secondary stage of the disease are usually not asthenic but pasty. With reference to the relations between infantile tuberculosis

and tuberculosis of adults, Ulrici holds the view that most cases of tuberculosis in adults are closely connected with conditions in the children—it may be a question of an activation of the primary pulmonary focus, the early dissemination focus or of the late dissemination. Ulrici does not think that in early infiltrations of adults it is a question of primary tuberculosis.

#### Observations on Tuberculin Sensitivity in Children

On 410 tuberculous children who in part were under observation for from nine to fifteen years, examinations on the behavior of the tuberculin sensitivity were reported by Dr. Viethen of the University Children's Clinic in Freiburg-im-Breisgau, 171 of these 410 children lived in the same environment with patients having open tuberculosis and were thus exposed to infection. During the long observation period, a reduction of the sensitivity to tuberculin was not demonstrable but rather an increase. Furthermore, no relation between sensitivity to tuberculin and the activity or form of the tuberculous processes could be ascertained. The possibility of superinfection had likewise no perceptible influence on the degree of sensitivity to tuberculin and the activity of the disease. Finally, the examinations showed that no prognostic conclusions could be based on the degree of the local reaction.

#### Purified Tuberculin

The constantly increasing cutaneous application of tuberculin for diagnostic purposes induced the government testing center for tuberculins to institute a series of tests on the cutaneous activity of tuberculins. Prof. E. Kuster has therefore worked out an exact testing method for the cutaneous action of tuberculins through intracutaneous inoculation into tuberculous guinea-pigs, in comparison with the standard tuberculin. It was found that the cutaneous value of whole tuberculins applied to guinea-pigs is not applicable to man, since man reacts cutaneously to the various substances combined with the whole tuberculin. Kuster therefore applied the Willstatter method to bring the tuberculins up to a high degree of purity. On applying the tuberculins intracutaneously and subcutaneously, it was found that in whole tuberculin two different substances, separable from each other, are present, one of which acts on the skin and the other on the tuberculous focus, the so called *toadstool*. By means of dialysis it proved possible to remove from the whole tuberculin all but 10 per cent of the *toadstool*. In this manner a tuberculin with a predominant amount of substance acting on the skin was obtained, the cutaneous employment of which on man avoids the danger of a general and focal action. By testing this substance on tuberculous and nontuberculous children the diagnostic value, compared with other tuberculins, for skin tests was demonstrated. This purified skin tuberculin appears suitable for the recently introduced serial examinations for the centripetal combating of tuberculosis.

#### Physician Allowed Compensation for Infection Contracted in Line of Duty

An assistant physician of St. Joseph's Hospital in Heerlen developed measles during his service in the measles pavilion of that hospital. The *Rijksverzekeringsbank* refused to intervene in spite of the law pertaining to industrial accidents, the management alleging that there was no question of sudden cause or of an event occurring in a comparatively short time. The central committee on workmen's compensation reversed the decision of the Roermond committee and that of the insurance management and conceded the physician's claim to an indemnity, basing its decision on the fact that the causative agent of the disease was introduced into the organism suddenly,

or within a short time, and that the infection was connected with his service. Physicians will hereafter be insured against the risks of infection to which they are exposed in the performance of their regular duties.

#### The First Netherlands Open-Air School

Netherlands' first open-air school was completed in July 1933. It consists of an examination room, refectory, restrooms and classrooms. It has accommodations for 100 pupils. Weak children are sent here on the recommendation of the consultation bureau for the combating of tuberculosis, in The Hague. Classroom work occupies the time from 9:10 a. m. to 12:15 p. m. After the noon meal the children rest from 1 to 2:30 and then resume their studies until 4:10 p. m. The late afternoons are devoted to physical exercise and manual training. In instruction, an endeavor is made to follow the standards of the regular primary school and at the same time to give more individual attention to the pupils.

#### Goiter in Children of School Colonies

Dr. Koopal's study of the goiter problem in the Netherlands was begun in 1932. He examined 1,502 boys and 1,509 girls and found 23 per cent affected with goiter, 16.5 per cent of the boys and 28.3 per cent of the girls. The percentage increases with the age, reaching the maximum at about age 12 for the boys and ages 8-12 for the girls. Dr. Koopal mentions other regions besides those studied particularly, in which thyroid patients are encountered. His conclusion is to the effect that goiter does not constitute an obstacle to the placing of children in school colonies.

#### The Institute of Criminology in Leyden

Prof. Dr. L. Van Italie, Mr. J. M. Van Bemmelen, Dr. E. Carp, L. Hulst, Dr. A. J. Steenhauer and Dr. D. Wiersma, who created the Institute of Criminology of Leyden, are planning to give next winter a series of lectures with demonstrations and tests. At each session two topics will be treated, and after the lectures the question will be thrown open for general discussion. Problems of poisoning and the psychological examination of criminals will be taken up first.

#### Reports on Weil's Disease

Two articles on Weil's disease appeared recently in the *Nederlandsch Tijdschrift voor Geneeskunde*. In the first, Kramer reports twenty-four observations on Weil's spirochetosis without icterus and describes the most marked symptoms for the diagnosis of these incomplete types, among which one may emphasize redness of the conjunctiva and the muscular signs. He divides the cases observed into four groups. In addition to forms of general infection without localized symptoms, he cites seven cases of nephritis and four in which the disease evolved exclusively in the form of an acute meningitis. Kramer refers to the recent monograph of Troisier and Boquien, whose indications—although secured of course in an entirely independent manner—agreed with his own. The occupation of the first patient examined by Troisier in 1926 (abattoir butcher) is in line with the discovery of several cases of Weil's disease in the abattoirs of Rotterdam (infested by many rats). One point to notice in the French cases is the normal (or even markedly increased) sugar content of the cerebrospinal fluid. Kramer is inclined to associate this with the fact that the pancreas also may be involved.

In the second article, Postmus recalls that the observations made by different authors do not agree with the results of the seroreaction in former patients with Weil's disease. Nineteen cases were studied at the Division of Tropical Hygiene in the Colonial Institute of Amsterdam. The studies extended to the seventeenth year after the infection. They revealed that in

the Netherlands the agglutinins and the lysins were preserved for many years in the blood of patients who had been affected with leptospirosis. This result is in accord with that of Pettit but is different from that secured by other authors. Possibly (as in other diseases) the immune bodies disappear more rapidly from the organism in the tropical region. Furthermore, the leptospires of Sumatra differ from the typical leptospirosis of Weil in Europe.

## ITALY

(From Our Regular Correspondent)

May 31, 1934

### The Health of the Italian Army

From the recently published annual report on the health of the Italian army for 1930, it appears that the morbidity per thousand among the noncommissioned officers and enlisted men dropped to 522, as against 546 for the previous year. The mortality was 27 per thousand of the average number enlisted. The average daily number of soldiers confined to their beds was twenty-two per thousand, which was an increase of two over the preceding year. The average duration of hospital care was eighteen days for persons admitted to the military hospitals, and five days for those under observation.

The highest morbidity was among the newly enlisted carabinieri, who are enrolled as volunteers at the age of 18 and are subjected to intensive drill and instruction. The morbidity increased in May and June, in which the greatest number of recruits are under arms, and reached the maximum in July.

From the standpoint of occupation of soldiers before being called to the colors, the morbidity from infectious diseases was less among the agricultural groups and more among the industrial and commercial groups.

The most frequent causes of death were tuberculosis (60.88 per hundred thousand of the average enlisted force, and covering 22.6 per cent of the deaths from all causes) and diseases of the respiratory apparatus. The lowest mortality was in the engineer corps and the highest was among the *granatieri*, chiefly because of accidents. The highest mortality was in the month of August (1.02 daily for each hundred thousand effectives), the lowest was in January (0.57). The number of soldiers eliminated as a result of medicolegal examinations was 24.54 per thousand effectives.

The most frequent diseases and sicknesses were the mild states of general malaise (227.4 per thousand patients). Of the disorders of the respiratory apparatus, pleuritis constituted 11.8 and pneumonia 9.5 per thousand. Of the infectious diseases, syphilis accounted for 52.2 per thousand, mumps for 25.2, malaria for 16.3, tuberculosis for 4.5, typhoid for 2.9, and diphtheria for 0.1 per thousand.

Only two soldiers were admitted to the hospital for acute alcoholism during the whole year.

The number of surgical operations performed in the military hospitals was 5,495 with an additional 3,361 minor interventions. The large number of operations was due to the radical treatment of inguinal and serotal hernia (1,028), the next in order were appendectomy (320), phlebotomy (17) and mastoidotomy (130).

During the year, 1,616 patients were admitted to the military hot springs resorts.

### New Senators Among the Physicians

In addition to those mentioned in a previous letter, Profs. Luigi Devoto, Giuseppe Muscatello, Guido Salvi and Giuseppe Orio were recently chosen as senators.

Professor Devoto is of the University of Milan, where he established and is the director of the chair of clinical aspects of occupational diseases. He has carried out important research on pellagra and ancylostomiasis, the results of his studies hav-

ing been published by special journals, such as *Il lavoro* and *Le malattie del lavoro*. Another important field of action of Professor Devoto has been the problems of Italian hydrologic and climatic resorts. Many of his pupils occupy today chairs in universities.

Professor Muscatello is director of the surgical clinic in Catania. He has been rector of the Università degli studi di Catania and dean of the faculty of medicine.

Prof. Guido Salvi is occupant of the chair in human anatomy and rector of the University of Naples. Of his many publications, the best known are those on a new method of topography of the rolandic fissure and the fissure of Sylvius. He has published treatises on anatomy and a manual of dissection.

Professor Orio is director of the Clinica oculistica of the University of Rome, president of the Società oftalmologica italiana and of the Fondazione per gli studi oftalmologici e per la profilassi oculare.

### The Surgical Society of Pavia

At a recent meeting of the Società medico chirurgica di Pavia, Zavattari spoke on the frequency of schistosomiasis of the bladder in Fezzan. Examining many samples of water and many persons in that region of Africa in 1933, the speaker found that *Bullinus contortus* is widely diffused in Fezzan. The persons affected by the disease ranges around 50.6 per cent of the total population, reaching the maximum in the children, almost all of whom present ova of *Schistosoma haematobium* in the urine.

Trabattori reported the results of research on tubercle bacilli with the Lowenstein method on the blood and the spinal fluid of patients with disorders of the nervous system. Examining thirty-six samples of blood from patients with dementia praecox, multiple sclerosis and chorea minor, he secured constantly negative results. He also found negative eighteen samples of spinal fluid from psychopathic patients and five samples of spinal fluid from patients with pulmonary tuberculosis in an advanced state. The speaker concluded therefore that the statements of Lowenstein cannot be accepted, at least not in nervous diseases.

Monti gave the results of experiments at the Policlinico di Pavia on the contaminations of the air, fogs and snow. The fogs, so frequent in the plain of Lombardy, collect germs, dusts and extraneous gases in the air but to a varying extent, depending on the meteorological conditions. The winds, although they stir up dust and thus disseminate various germs and spores, disperse fumes, gases and fine dust and hence, on the whole, tend to purify the air.

In low-lying fogs without wind, all the impurities of the air remain near the earth, germs develop ten times more rapidly than in the presence of wind, and among these *Bacillus fusiformis* abounds. In addition to mineral dusts there are many coal particles, with various products of combustion, and the gases given out by industrial establishments. With sudden changes of temperature, if there is no wind, the smoke from chimneys and the industrial gases and vapors are thrown out into the lower strata of the atmosphere. If these gases and vapors attain a certain concentration, they may give rise to disasters such as were observed in December 1931 in the valley of the Meuse.

### Prophylaxis of Venereal Diseases

The public health service has recently sent to the prefects regulations for the prevention of venereal diseases, considered with special reference to heredity. The provisions concern chiefly aid to syphilitic women during pregnancy and to the new-born with congenital syphilis. Obstetricians should investigate with great care to discover the possible presence of syphilitic manifestations in pregnant women and serologic examinations should be made in all suspected cases. Pregnant syphilitic women should be admitted to a special department and not to the ordinary ward for syphilitic women.

Orphan asylums should provide special wards for syphilitic persons. The new-born should not be admitted until a serologic test for syphilis has been applied to both mother and child. The aid to syphilitic children admitted to orphan asylums should ordinarily be given within the institution, but after the nursing period is completed it may be continued in special institutions.

In the children's hospitals and the pediatric clinics, centers should be established for congenital syphilis and infantile syphilis, in which mothers will find facilities that will encourage them to take their children there.

The public health service took this opportunity to urge provincial physicians to determine the best method to collect data on cases of congenital syphilis.

### Vaccination with Anatoxin

Ramon, Timbal and Nelis communicated recently to the Royal Academy of Medicine of Belgium their observations on 14,000 children vaccinated with anatoxin. Vaccination with anatoxin has been found to be practically harmless. Anatoxin properly prepared and controlled cannot cause the slightest specific intoxication. The reactions are transitory and never dangerous. Vaccination never has any bad effects on the later development of the vaccinated child. The injection of anatoxin is not followed by a negative phase. It does not render the vaccinated subjects more sensitive to diphtheritic infection or to any other disease. If the anatoxin possesses the requisite number of flocculation units and is injected according to prescribed rules in the doses and with the observation of the intervals recommended, it produces immunity in a high proportion of persons vaccinated, and the immunity conferred endures for a long period. Applied in two injections (1 and 2 cc, with an interval of three weeks, and with anatoxin having at least 20 antigenic units), vaccination will develop an immunity that yields a negative Schick reaction in from 99 to 100 per cent of persons vaccinated. It is the preferred method for individual and collective prophylaxis of diphtheria.

### Thrombophlebitis of the Cavernous Sinus

At the annual meeting of the Groupement belge d'études oto-neuro-ophtalmologiques et neuro-chirurgicales, Dr Moreau discussed thrombophlebitis of the cavernous sinus. The paths that infections follow are important to know. The cavernous and the contiguous sinuses form a venous crossway, which surrounds the hypophysis and constitutes from the venous point of view an equivalent of the circle of Willis.

Although every thrombosis has an infectious origin, the author holds that there are sufficient reasons to grant a certain independent existence to the two groups set up by older writers: marantic thrombosis and inflammatory thrombosis. The former is always due to a general disorder and has its seat usually in the unpaired sinuses. When it extends to the paired sinuses it does so symmetrically. Inflammatory thrombosis invades the paired sinuses and is commonly asymmetrical.

In the majority of cases, thrombosis of the cavernous sinus is a purely inflammatory thrombosis. As regards preventive treatment, when the inoculation lesion is facial intervention should be as prompt as possible by means of wide electro-coagulation with the electric knife and extensive coagulation, which should go considerably beyond the infected area. With an electric loop the column of coagulated tissue is removed, which leaves a pit effecting the drainage of the thrombosed veins of the adjacent area.

In cases of tonsillar, sphenoidal, auricular or maxillary origin, the fundamental indications are early and thorough treatment,

whenever possible, of the original lesion. In spite of early drainage, it is sometimes difficult to check the progress of infection. From the standpoint of treatment of thrombophlebitis of the cavernous sinus, the author pointed out that the various technics proposed were all too radical to be applied to patients so gravely intoxicated.

Surgery is not always contraindicated, but careful selection of cases is needed. The time of the appearance of the cavernous sinus and the rapidity of the evolution are the principal criteria as to the attitude to be observed.

No intervention should be attempted in the cases with rapid evolution or in those that have evolved too far. With regard to the operative technic, the author sides with the views of Wells P. Eagleton. He pointed out that ligation of the internal carotid artery, which relieves the strain on the thrombosed sinus, is the first distinct advance made in the treatment of thrombophlebitis of the cavernous sinus.

### Malaria in Tropical Africa

Dr Rodhain, of the Institut royal colonial belge, recently lectured on malaria in tropical Africa, which is the most important factor opposing the settlement of Europeans in the tropics. He emphasized the great difference between the malarial regions of the temperate zone, where the malaria season lasts only a few months, and the tropical regions with endemic malaria, in which the anopheles are less numerous during the dry season but do not disappear.

The crusade against the mosquito cannot of itself break the cycle of propagation. Chemotherapy—quinine, on the one hand, and plasmochin, on the other hand—gives positive results in the carrier of parasites. But, as a product that will protect man against the sporozoites transferred from the mosquito is not available, he concluded that in the regions where malaria is endemic the curative and gametocidal action will not give permanent results unless the crusade against the mosquito is carried on effectively. Is the sterilization of the native, who constitutes the great reservoir of virus, possible? The chemotherapeutic products are expensive. The vast undertakings to eradicate malaria give variable results, depending on the peculiar topographic and climatic conditions. There is justification for expecting a chemical product that is truly prophylactic. The extension of the cultivation of cinchona trees may furnish a powerful aid.

### Leprosy in the Belgian Congo

In a population of 443,700 in the region of Nepoko, Belgian Congo, 4,600 leprosy subjects have been detected. The Red Cross Society assumed the task of ferreting out these cases and of rendering the necessary aid. It has concentrated 700 leprosy subjects in three villages and is planning to establish further villages. It does not appear likely that these leprosy colonies will be self supporting.

## Marriages

WILLIAM ANDREW HORSLEY GANTT to Miss Mary Gould Richardson, both of Baltimore, June 23.

JOHN WILLIAM CAMP, Cambridge, Ohio, to Miss Emma Marie Gordon at Somerset, June 17.

NICHOLAS PADIS, Boston, to Miss Kively Evangelides of New Brunswick, N. J., April 29.

MORGAN CUTTS, Bridgeport, Conn., to Miss Katharine B. Knox of Baltimore, June 30.

T. MAURICE AHLQUIST to Mrs. Wilbur N. Joyner, both of Spokane, Wash., June 4.

WILLIAM E. BUEHLER to Alice F. Willson, both of Chicago, July 26.

## Deaths

**Edward Grant Seibert** \* Washington, D C, Columbian University Medical Department, Washington, 1893, counselor of the Medical Society of the District of Columbia, formerly clinical professor of laryngology, rhinology and otology at his alma mater served during the World War, fellow of the American College of Surgeons, aged 68, died, June 30, of paratyphoid fever, diverticulitis and perforation of the urinary bladder

**George Walter Holden** \* Denver, University of Vermont College of Medicine, Burlington, 1895, fellow of the American College of Physicians and member of the American Climatological and Clinical Association formerly medical director of the Agnes Memorial Sanatorium, aged 67, died, July 12, of coronary thrombosis and arteriosclerosis

**Frederick William Mulligan**, Petrolia, Ont, Canada, Trinity Medical College, Toronto, 1893, L R C S, Edinburgh, 1894, L R C P, London, and M R C S, England, 1895, formerly member of the board of education, county coroner, on the staff of the Charlotte Eleanor Englehart Hospital, aged 61, died, May 14, of pneumonia

**David A Hutchinson**, Nashville, Ark, College of Physicians and Surgeons, Baltimore, 1880, member of the Arkansas Medical Society, past president and secretary of the Howard County Medical Society, past president of the county board of health, formerly mayor of Nashville, aged 85, died, May 27, of senility

**Thomas Henry Mays**, Freeland, Pa, University of Pennsylvania School of Medicine, Philadelphia, 1910, member of the Medical Society of the State of Pennsylvania, member of the school board aged 49, died suddenly, July 1, at his summer home in Ocean City, N J, of coronary disease

**Orlando Fenton Lowry**, Cambridge, Ohio, Starling Medical College, Columbus, 1889, formerly a pharmacist, at one time member of the board of education, aged 78, died, April 12, in the Wells Hospital, of partial intestinal obstruction caused by inflammation of the gallbladder

**Samuel L Lingle**, Paoli, Ind, University of Louisville (Ky) School of Medicine, 1891, member of the Indiana State Medical Association, served during the World War, aged 66, died, June 15, in St Edward's Hospital, New Albany, following an operation for appendicitis

**Ralph Taylor Shipley** \* Canton, Ohio, Western Reserve University Medical Department, Cleveland, 1910, served during the World War, fellow of the American College of Surgeons, aged 50, on the staff of the Aultman Hospital, where he died, July 7, of acute leukemia

**J Wildy Ladouceur**, Lewiston, Maine School of Medicine and Surgery of Montreal, Que, 1910, member of the Maine Medical Association, served during the World War, on the staff of St Mary's Hospital, aged 46, died suddenly, June 25, of heart disease

**Walter Abner Scott** \* St Johns, Mich, University of Michigan Medical School, Ann Arbor, 1904, past president of the Clinton County Medical Society, on the staff of the Clinton Memorial Hospital, aged 59, died, June 9, of coronary occlusion

**William Henry Leith**, Lancaster, N H University of Vermont College of Medicine, Burlington 1883 member of the New Hampshire Medical Society on the staff of the Lancaster Hospital, aged 75, died, April 3, of pernicious anemia

**Albert S J Stovall** \* Elberton Ga, University of Georgia Medical Department Augusta, 1886 past president of the Elbert County Medical Society, formerly state senator, aged 72, died June 21 in the Elberton County Hospital, of nephritis

**Charles William Hutchinson** \* Concord, Mass Harvard University Medical School Boston 1917, on the staff of the Concord Hospital aged 49, died June 26 in the Baker Memorial Hospital, Boston, of subacute bacterial endocarditis

**Russell Andrew Patrick**, Marshalltown Iowa State University of Iowa College of Medicine, Iowa City 1932 member of the Iowa State Medical Society, aged 32, died, June 22, in the Evangelical Deaconess Hospital of nephritis

**Robert Benjamin Ginn**, Frankfort, Ky Kentucky School of Medicine Louisville 1893, member of the Kentucky State Medical Association for eight years coroner, aged 62 died, June 28 of hypernephroma of the right kidney

**George W Burnett**, Whitesburg Ga, Southern Medical College, Atlanta, 1878, member of the Medical Association of

Georgia, formerly member of the state legislature and county board of education, aged 80, died, June 19

**Homer Clifton Oatman Jr**, San Diego, Calif, McGill University Faculty of Medicine, Montreal, Que, Canada, 1931, member of the California Medical Association, aged 29, died, June 16, of subacute bacterial endocarditis

**Medwin Leale** \* New York, Columbia University College of Physicians and Surgeons, New York, 1896, veteran of the Spanish-American War, aged 60, died, June 30, in St Luke's Hospital, of myelogenous leukemia

**James Theodore Sedgwick**, Litchfield, Conn University of the City of New York Medical Department, 1885, member of the Connecticut State Medical Society, aged 71, died suddenly, July 15, of angina pectoris

**Murdock Angus MacKay**, Tisdale, Sask, Canada, Queen's University Faculty of Medicine, Kingston, Ont, 1911, for many years member and chairman of the school board, aged 54, died, April 1, in Victoria, B C

**Walter Russell Sanders**, Derry Village, N H, Bennett College of Eclectic Medicine and Surgery, Chicago 1884, member of the New Hampshire Medical Society, aged 71, died, June 29, of heart disease

**Alexander Holland Conrad**, Perris, Calif, University of Michigan Medical School, Ann Arbor, 1932, member of the California Medical Association, aged 33, died, May 10, of a self inflicted bullet wound

**Leander Young Ketcham**, San Diego, Calif, University of Vermont College of Medicine, Burlington, 1880, aged 83, died, May 14, of bronchopneumonia, carcinoma of the prostate and arteriosclerosis

**Andrew W Goodwin**, Oil City, Pa, Cleveland Medical College, 1893, member of the Medical Society of the State of Pennsylvania, on the staff of the Oil City Hospital, aged 64, died, June 18

**Walter Hibbard Lewis**, Pendleton, Ind, University of Pennsylvania School of Medicine, Philadelphia, 1873, aged 85, died, May 31, of hypostatic pneumonia following fracture of the hip bone

**Wilfred Otto Louis Lellmann** \* New York, Columbia University College of Physicians and Surgeons, New York, 1914, aged 68, died, June 8, in the Lenox Hill Hospital, of heart disease

**Henry Lyman** \* Canton, Mass, Harvard University Medical School, Boston 1912, served during the World War, aged 54, died, June 15, of thrombophlebitis and pulmonary embolism

**Roscoe E Schindel** \* Omaha, Baltimore Medical College, 1897, formerly professor of diseases of the stomach, John A Creighton Medical College, aged 63, died, June 15, of angina pectoris

**Max Adolph Wechsler**, Edgemere, N Y, University of the City of New York Medical Department, 1893, member of the Medical Society of the State of New York, aged 61, died, June 6

**Michael M Rankin**, Ridgway, Pa, Medical College of Ohio, Cincinnati, 1876, member of the Medical Society of the State of Pennsylvania, aged 82, died, April 12, of gangrene

**Arthur David Morgan**, Alberni, B C, Canada, McGill University Faculty of Medicine, Montreal, Que, 1901, served with the Canadian Army during the World War, died recently

**James Joseph Rock**, Ryan, Iowa, State University of Iowa College of Medicine, Iowa City, 1916, served during the World War, aged 46, died, June 16, in a hospital at Cedar Rapids

**William J Esch**, Cleveland, University of Wooster Medical Department, Cleveland, 1881, aged 73, died, June 12, of empyema of the gallbladder and congestive heart failure

**John W Williams**, Harvest Ala, Memphis (Tenn) Hospital Medical College, 1895, veteran of the Spanish-American War, aged 76, died, May 12 of hypostatic pneumonia

**William Ferguson Torbitt**, Bennet, Neb, University of Maryland School of Medicine Baltimore, 1903, also a druggist, aged 80, died, May 13, in a hospital at Lincoln

**Roy Wesley Klaus**, Chicago, Hahnemann Medical College and Hospital Chicago 1912 aged 47 died July 11, in St Francis Hospital, Evanston, of acute appendicitis

**William T McKay** \* Long Beach, Calif, Rush Medical College Chicago 1881, a fellow of the American College of Surgeons, aged 73, died, June 12 of angina pectoris

**Joseph Douglas Malcolm** \* New York, Columbia University College of Physicians and Surgeons, New York, 1904, aged 60, died, June 20, of carcinoma of the rectum.

**St Clair Streett**, Kansas City, Mo., University of Maryland School of Medicine, Baltimore, 1880, aged 75, died, June 27, of arteriosclerosis and cerebral hemorrhage

**Mark Hugh Hudgings**, Caruthersville, Mo., Missouri Medical College, St Louis, 1887, member of the Missouri State Medical Association, aged 69, died, May 13

**Gordon Russell MacKay**, Hagersville, Ont., Canada, University of Western Ontario Medical School, London, 1927, aged 31, died, June 4, in an automobile accident

**Florence B MacRae** ☉ Chicago, Eclectic Medical College, Cincinnati 1926, on the staff of the Woodlawn Hospital, aged 44, died, July 9, of carcinoma of the liver

**Samuel Kuner**, Long Island City, N. Y., University of Illinois College of Medicine, Chicago, 1926, aged 39, died, June 28, of leukemia and exophthalmic goiter

**Clarence Augustus Cobleigh**, Chattanooga, Tenn., Chattanooga Medical College, 1897, member of the Tennessee State Medical Association, aged 62, died, June 15

**George William Finley** ☉ Brazil, Ind., Medical College of Indiana, Indianapolis, 1890, aged 79, died, June 18, in the Clay County Hospital, of chronic meningitis

**Patrick Joseph William Conran**, San Francisco, Cooper Medical College, San Francisco, 1894, aged 65, died, May 15, of cerebral hemorrhage and arteriosclerosis

**Chambers D Calhoun**, Elburn, Ill., Jefferson Medical College of Philadelphia, 1884, aged 75, died, July 11, in the Community Hospital, Geneva, of heart disease

**Theodore L Carriere** ☉ St Louis, Homeopathic Medical College of Missouri, St Louis, 1895, formerly deputy coroner, aged 62, died, June 21, of heart disease

**Chester John Montgomery**, Los Angeles, Marion-Sims Beaumont Medical College, St Louis, 1903, aged 54, died, May 12, of hemiplegia and hypertension

**John Francis Harte**, Athens, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1887, formerly coroner for Leeds and Greenville, died, May 14

**George Cramer Connett**, Morristown, N. J., Hahnemann Medical College and Hospital, Chicago, 1891, also a lawyer, aged 69, died, July 5, of heart disease

**Arthur Hart Remington**, Los Angeles, University of Pennsylvania School of Medicine, Philadelphia, 1898, aged 57, died, April 17, of cirrhosis of the liver

**Rolland Tyson Winstead**, Rocky Mount, N. C., Meharry Medical College, Nashville, Tenn., 1923, served during the World War, aged 44, died, May 28

**William Joseph Winters**, Philadelphia, Jefferson Medical College of Philadelphia, 1905, aged 53, died, June 22, of coronary thrombosis and myocarditis

**William Ethelbert Hall**, Los Angeles, College of Physicians and Surgeons, Los Angeles 1912, aged 47, was found dead, June 25, of cyanide poisoning

**William Starick Ruch**, Carlisle, Pa., Jefferson Medical College of Philadelphia, 1888, formerly county coroner, aged 71, died, June 28, of heart disease

**William A Lockett**, McEwen, Tenn., University of Louisville (Ky.) School of Medicine, 1865, Civil War veteran, aged 96, died, June 11, of senility

**Willet H Loughlin**, Bloomington, Mich., College of Physicians and Surgeons of Chicago, 1886, aged 76, died, June 21, of carcinoma of the liver

**Lawrence A Hoffmeyer**, Superior, Wis. (licensed in Wisconsin in 1924), aged 70, died, June 8, of Hodgkin's disease, arthritis deformans and prostatitis

**John Joseph Sheridan**, New York, Fordham University School of Medicine, New York, 1912, on the staff of the Seton Hospital, aged 55, died, June 24

**Harry Wood** ☉ Batchtown, Ill., St Louis University School of Medicine, 1905, served during the World War, aged 55, died July 4, of endocarditis

**Robert Hunter Robinson**, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1873, aged 87, died, June 15, in a local hospital

**Charles Haight Conover**, Philadelphia, Hahnemann Medical College of Philadelphia, 1879, aged 75, died, July 2, of a self-inflicted bullet wound

**Claude J Harley**, Bronson, Mich., Chicago College of Medicine and Surgery 1913, aged 47, died, July 11, of chronic nephritis and myocarditis

**Armstrong M Spence**, Lucknow, Ont., Canada, Trinity Medical College, Toronto, 1889, died, June 2, in the Oshawa (Ont.) General Hospital

**Louis M Crow**, Des Arc, Ark., University of Nashville (Tenn.) Medical Department, 1907, aged 53, died, June 10, of cerebral hemorrhage

**John Henry Young Grant**, Niagara Falls, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1886, aged 74, died, June 25

**Henry Ward Parker**, New Bedford, Mass., Harvard University Medical School, Boston, 1890, aged 85, died, May 24, of chronic myocarditis

**William H Horr**, Cleveland, Homeopathic Hospital College, Cleveland, 1880, aged 75, died, July 4, of an accidental overdose of morphine

**Frederick W Belknap**, Chicago, Northwestern University Medical School, Chicago, 1894, aged 66, died, July 16, of cerebral hemorrhage

**Walter C Lambert**, Wyandotte, Mich., Detroit College of Medicine, 1886, formerly mayor, aged 70, died, June 8, of cerebral hemorrhage

**Samuel F Love**, Morgan City, Miss., University of Tennessee Medical Department, Nashville, 1881, aged 76, died, May 16, in Oklahoma City

**William Roscoe Jacobs**, Stockton, Calif., Cooper Medical College, San Francisco, 1910, aged 46, died, May 20, of poison, self administered

**Stanley Edward Somers** ☉ East Tawas, Mich., Detroit College of Medicine and Surgery, 1930, aged 33, was shot and killed, July 1

**Francis Leo Daly Scanlan** ☉ Syracuse, N. Y., Syracuse University College of Medicine, 1908, aged 46, died, June 28, of acute nephritis

**George Phillips Waller Sr**, Los Angeles, Jefferson Medical College of Philadelphia, 1877, aged 80, died, May 18, of acute myocarditis

**August H Niemiller**, Browns, Ill., Medical College of Ohio, Cincinnati, 1875, aged 81, died, June 14, in the Olney (Ill.) Sanitarium

**John Huston Johnson** ☉ Glenmoore, Pa., Jefferson Medical College of Philadelphia, 1907, aged 57, died, April 17, of angina pectoris

**Frank Wickham**, Corona, N. Y., Bellevue Hospital Medical College New York, 1876, Civil War veteran, aged 86, died, May 18

**David Henry Worthington**, Aurora, Ill., Rush Medical College, Chicago, 1879, aged 83, died, June 2, of chronic myocarditis

**Wallace Nathaniel Price** ☉ Gardiner, Maine, Medical School of Maine, Portland, 1894, aged 63, died, June 16, of endocarditis

**Frank Leslie Riegel**, Springfield, Ohio, Columbus Medical College, 1891, aged 74, died, June 28, in the Springfield City Hospital

**Philip Reide Kaiser**, Tottenham, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1926, aged 32, died, June 3

**Albert Irvin Moore**, Fayetteville, Ark., University of Michigan Medical School, Ann Arbor, 1884, aged 71, died, May 9

**John Robert Dales**, Dunbarton, Ont., Canada, Victoria University Medical Department, Coburg, 1885, aged 78, died, May 5

**Winfred W Nuss**, Elkland, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1892, aged 67, died, May 1

**George McDuffie Lackey**, Staples, Texas, Memphis (Tenn.) Hospital Medical College, 1896, aged 66, died, June 14

**Andrew Grant**, Beaverton, Ont., Canada, University of Toronto Faculty of Medicine, 1877, aged 80, died, May 23

**Nicholas M Spranger**, Detroit, Detroit College of Medicine, 1892, aged 73, died, June 26, of cerebral hemorrhage

**Jacob Glahn**, Owensboro, Ky., University of Louisville (Ky.) School of Medicine, 1885, aged 74, died, April 28

**James O Robinson**, Spokane, Wash., Hospital College of Medicine, Louisville, Ky., 1885, aged 72, died, March 22

**Archie Cole** ☉ Pampa, Texas, St Louis University School of Medicine 1909, aged 50, died, June 21, of uremia

**George W Kirk Jr**, Curtice, Ohio, Toledo Medical College, 1888, aged 83, died, May 29

**John Edward Reeve**, Toronto, Ont., Canada (licensed in Ontario in 1877), died, May 10

## Correspondence

### "CHOLESTEROLEMIA AND THYROID DISORDER"

To the Editor—I have read with interest your editorial of July 14 on cholesterolemia and thyroid disorder

The reader who has not followed the evolution of the subject would doubtless conclude, from what you have written, that the discovery of the relationship between thyroid activity and the cholesterol content of the blood is a very recent one. For this reason it might be of interest to mention that Lande and I pointed out in 1922 (*Studies on Blood Lipoids, Arch Int Med* 30 563 [Nov] 1922) and supported by extensive protocols the existence of an inverse relationship between thyroid activity and cholesterolemia. In subsequent publications (*Thyroid Therapy and Thyroid Tolerance in Chronic Nephrosis, THE JOURNAL*, Sept 18, 1926, p 913, *Ueber Diabetes albinuricus, die sogenannte chronische Nephrose, Arch f Verdauungsstr* 44 31 [Aug] 1928) I have repeatedly discussed this subject and have utilized the principles involved as an index for thyroid therapy in nephrotic states—a form of treatment that is widely used.

Dr Hurxthal's work from the Lahey Clinic, on which your editorial is based, constitutes a welcome confirmation and amplification of our investigations.

ALBERT A. EPSTEIN, M.D., New York

### LYMPHATICS OF THE SKIN

To the Editor—My attention has been called to your editorial "Lymphatics of the Skin," which appeared in *THE JOURNAL*, May 19. In this article you say "While this superficial lymphatic plexus has been described before by anatomists, it was supposed to represent local areas, each acting independently. With the technic mentioned, the wide connections of these anastomosing plexuses were observed for the first time" (italics mine). This statement, I regret to say, does not agree with recorded facts. Prof. H. Rouviere in his work "Anatomie des lymphatiques de l'homme" states (p. 4) that it was Mascagni (*Vasorum lymphaticorum corporis humani*, p. 75 and pl. IV) who first established the connection between the superficial and deep lymphatics. In Rouviere's description of the lymphatics one also reads (p. 1 line 22) "Quand une rescan est tres riche, les vaisseaux qui le forment peuvent etre disposes sur plusieurs plans. Dans ce cas, les vaisseaux superficiels sont les plus petits et les profonds les plus gros. Lorsque cette disposition se presente, on dit parfois qu'il existe deux reseaux, l'un superficiel, l'autre profond, bien qu'il ne s'agisse la que d'un meme reseau" (Wherever a network is abundant, the capillaries that form it may be arranged in several layers, in which case the superficial capillaries are the smaller and the deeper of larger size. When this arrangement is encountered, we speak of two systems of networks, a superficial and a deep, although they function jointly as one network). On page 3, line 18: "Aussitot apres leur origine dans le reseau dermique, une partie des vaisseaux superficiels chemine superficiellement dans le pannicule adipeux—les autres traversent ce pannicule et la fascia superficialis et se placent dans la couche de tissu cellulaire souscutane." (Immediately after their origin in the lymph networks of the skin, a portion of the superficial lymph vessels run superficially in the superficial fascia, while the others traverse the superficial fascia and come to lie in the subcutaneous cellular tissue.) And on page 3 line 22: "Les anastomoses entre vaisseaux lymphatiques voisins sont frequentes. Elles diminuent de nombre a mesure qu'on s'eloigne du reseau d'origine—Il existe aussi des anastomoses qui

etablissent, a travers la ligne mediane, une liaison entre les lymphatiques des deux moities du corps. Cette liaison est assuree, suivant les regions, soit par des anastomoses qui unissent entre eux les collecteurs voisins, soit a la fois par les reseaux et par des canaux anastomotiques" (Anastomoses between neighboring lymph vessels are frequent, these, however, diminish in number as the lymph vessels recede from their networks of origin. There also exist anastomoses which establish connections across the median line between both halves of the body. Such connections are assured according to the region either by anastomoses which unite neighboring lymph collecting vessels, or by means of lymph-capillary networks and anastomotic channels at one and the same time). Finally, throughout his work, H. Rouviere shows clearly (for instance, figs. 60-63) the continuation of the superficial with the deep lymphatics.

M. J. TOBIAS, M.D., New York

### OVERDOSAGE OF SPINAL ANESTHETIC

To the Editor—The following case is of interest to the profession because of the large dose of spinal anesthetic administered with a subsequent almost fatal outcome. A white woman, aged 40, weighing 160 pounds (72.6 Kg.), with a systolic blood pressure of 140 and a diastolic blood pressure of 80, was given a spinal anesthetic for a cholecystectomy for hydrops of the gallbladder. Novocain crystals (a brand of procaine hydrochloride) dissolved in the patient's spinal fluid were injected into the third lumbar space. While the gallbladder contents were being emptied the patient became pulseless and stopped breathing. Cardiac and respiratory action was restored by means of subdiaphragmatic cardiac massage, epinephrine by vein and artificial respiration. The operation was terminated at this point by a cholecystostomy. The postoperative course was uneventful. As I had given and seen given many similar spinal anesthetics with the same drug with no untoward reactions, I could not explain this reaction until I noticed that the glass ampule used did not contain the usual 120 mg. but contained 500 mg. This ampule was not meant for spinal use but was used by mistake.

ALEXANDER ZABIN, M.D., Malvern, L. I.

NOTE—There seems to be no good reason for marketing 500 mg. ampules of novocain. These have not been accepted by the Council on Pharmacy and Chemistry. The largest dosage form accepted (Procaine-Abbott) is 200 mg.—Ed.

### PHYSICOTHERAPY—PHYSICAL MEDICINE

To the Editor—Medical practitioners strongly resented the ultimately successful scheme of a few lay cultists, aided by politicians, to force the "physiotherapist" clause into the new (1926) medical practice act of New York State. The officials of the American Medical Association accordingly dropped the terms physiotherapy and physiotherapist, as applicable to medical graduates, properly substituting those of physical therapy and physical therapist. It is to be regretted that some ill advised medical practitioners and institutions still adhere to the objectionable nonmedical terms.

Otto Veraguth, M.D., professor of physical medicine at the University of Zurich, in his presidential address at the annual meeting (at that institution, Jan. 29, 1934) of the International Society of Medical Hydrology, spoke "In Defense of a Name" and as reported in the *Archives of Medical Hydrology*, May, 1934, pages 241-242, said in part: "I take as my point of departure my criticism of two titles often used for physical treatment, or physical medicine, namely, physiotherapy and 'nature medicine' (naturheilkunde). Both these terms are based on an unscientific mysticism because the description is too ill defined. For we do not treat our patients nowa-

days only by climate, waters or baths, but by many technically differentiated forms of such natural forces. No one would deny that behind all these processes the *vis medicatrix naturae* is at work as a driving force.

What the *medicus curans* provides to the *natura sanans* is intelligent removal of obstacles, rapid preparation of the way, provision of supplementary forces working in the same direction and a strengthening of their striking force.

The description physiotherapy (or the English term physical medicine) is in direct and definite contrast to the inadequate, illogical and presumptuous terms physiotherapy and nature treatment. The adjective physical refers to the most exact of the natural sciences, physics. Physical treatment is therefore, properly speaking, that kind of treatment of disease the therapeutic agents of which are to be defined by the science of physics."

A B HIRSH, M D, New York

### MESENTERIC VASCULAR OCCLUSION WITH RECOVERY

*To the Editor*—The article by J R Green and C H Allen on mesenteric vascular occlusion with recovery (THE JOURNAL, July 7) is concise, frank and instructive. The case report seems to me, however, after a close study, to be one of volvulus of the small intestine secondary possibly to adhesions from the previous appendectomy. The two conditions give the same pathologic end result—gangrene from occluded blood supply—but as their etiology is so vastly different, as is also their prognosis, I thought it would be no mere quibbling to call this to your attention. The authors themselves mention the importance of looking for an etiologic factor in a vascular mesenteric thrombosis, but in their pathologic description they have pointed out none. Furthermore, the age of the patient, 24, would make a primary mesenteric thrombosis extremely rare, whereas it is entirely compatible with the usual age incidence of volvulus. I happened to be interested in this case because I performed a necropsy in a similar one several months ago at the Philadelphia General Hospital. The symptoms and pathologic observations were practically the same, except that the volvulus was due to adhesions around a large uterine fibromyoma.

NATHAN RALPH, M D, Eagleville, Pa

[NOTE—This suggestion was forwarded to Dr J R Green, who replies.]

*To the Editor*—The criticism is pertinent. We have no positive proof of the etiology in this case. Reference to the description of the gangrenous bowel that it was a straightened out piece of bowel lying parallel to the mesentery on the left side of the spinal column, with no kinking of the mesentery and no adhesions of the gangrenous bowel or any adjacent bowel or other viscera, makes it improbable that volvulus could have caused the interruption of the blood supply. The patient had no symptoms referable to the gastro-intestinal tract during the eight months interval between the appendectomy and the onset of the gangrenous bowel.

Two weeks before the onset of this disease the patient and three other persons took an automobile tour of several hundred miles. One other member of the party had acute appendicitis soon after returning home. He was operated on and a moderately acute catarrhal appendicitis was found with considerable free peritoneal fluid. Severe cramping pain followed at intervals for one month after this. He eventually recovered completely. The fact that two members of the party were attacked by a severe bowel malady is suggestive of food or bacterial poisoning with localized lesions of the bowel wall. Ulceration is known as one of the conditions leading to thrombosis of the mesenteric blood vessels. In the absence of bacteriologic confirmation we did not include this in the report of the case.

JOHN R GREEN, M D, Independence, Mo

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### DIABETES IN YOUNG BOYS

*To the Editor*—A boy aged 13, 48 inches (122 cm) tall weighing 60 pounds (27 Kg), has had diabetes mellitus for eleven years. His liver is enlarged extending almost to the navel. He looks like a patient with congenital hypopituitarism as evidenced by the height, the facies of an old man and absence of pubic hair. The diabetes has been difficult to control with a maintenance diet and from 10 to 20 units of insulin twice daily. The nonprotein nitrogen of the blood is 50 mg per hundred cubic centimeters. What relationship is there between the pituitary disturbance and the diabetes? Could marked benefit be expected from pituitary medication? If so what would be the dosage and which type of preparation should be given?

T A TAYLOR M D, Lufkin, Texas

*ANSWER*—Fortunately the boy is alive, although 5 inches below height for his age and 17 pounds overweight for his height. He is only paying a temporary penalty for a lack of diet during the first years following the discovery of insulin. It must be taken for granted that he like all other similar patients will get fat before he gets tall and unless he breaks the rule his greatest acceleration in height will not occur until between the ages of 15 and 19 years.

It is unnecessary to use pituitary preparations, but he should have at least 175 Gm of carbohydrate, 90 Gm of protein and 100 Gm of fat with insulin in sufficient amounts to keep him sugar free or nearly so and probably given in four doses. Whole thyroid gland, from 1 to 3 grains (0.065 Gm to 0.2 Gm) daily for months possibly would help. He would be a good subject for a boys' summer camp.

The high nonprotein nitrogen may not be significant, but it can be repeated and a two hour renal test performed. It would

### Record of Diet, Insulin and Growth of a Diabetic Child Whose Growth was Stunted by the Undernutrition Treatment of the Preinsulin and Early Insulin Era

Date	Height in Inches	Weight in Pounds	Carbo- hydrate Gm	Pro- tein Gm	Fat Gm	Calories	Units of Insulin	Age Years
1919	42	35	32	29	25	477	0	5
1922	44½	32	59	25	35	615	0	8
1922½	48	51	46	68	108	1,428	20	12
1927	48¾	58	79	67	112	1,592	20	13
1928	51¾	68	101	73	118	1,758	21	14
1929	52½	72	115	81	133	1,931	21	15
1930	53¾	80	129	83	135	2,063	33	16
1931	55½	88	172	90	144	2,344	51	17
1932	58¾	100	169	87	126	2,158	62	18
1933	63¾	126	169	87	126	2,158	64	19
1934	63¾	122	169	87	126	2,158	75	20

also be of interest to secure an examination of the eyes and a roentgen examination of the arteries of the legs.

Two examples of similar cases are given for encouragement. The onset of diabetes in one of these boys occurred in August 1919, at the age of 5½ years. His weight was 35 pounds (16 Kg) and his height 3 feet 6 inches (107 cm). From 1919 to 1922 he was treated with undernutrition, 30 calories per kilogram, and grew 2¼ inches (5.5 cm) but lost 3 pounds (1.4 Kg). From 1923 to 1926 a moderate state of undernutrition was continued and he grew 3¼ inches (9.5 cm) and gained 19 pounds (8.6 Kg). From 1927 on he received a higher caloric diet with from 80 to 172 Gm of carbohydrate, from 70 to 90 Gm of protein and from 116 to 144 Gm of fat. In 1934 at the age of 20 he is short but physically mature, taller than his mother and only just a trifle shorter than his father. His greatest acceleration of growth occurred between the ages of 16 and 19.

Another boy, in whom diabetes developed in 1920 at the age of 4 years, weighed 81 pounds (37 Kg) dressed and was 55½ inches (140 cm) in height in October 1932, when he was 16 years old. The treatment was changed and in February 1934 his weight was 97 pounds (44 Kg) dressed and his height was 4 feet 11 inches (150 cm). Thus in sixteen months he gained 16 pounds (7.3 Kg) and grew 3½ inches (9 cm), while his diet was increased from 101 Gm of carbohydrate, 51 Gm of protein, 74 Gm of fat and 25 units of insulin to 160 Gm of carbohydrate, 100 Gm of protein, 100 Gm of fat and 39 units of insulin. Greater acceleration of growth is expected in the next two years.

## PRURITUS BALNEA

To the Editor—Please advise the treatment of pruritus balnea. I have a case in which a man aged 65 for half an hour following a bath has most terrible itching which nothing has relieved. Soda and starch baths have been used without success. The skin shows no lesions what ever. Please omit name. M D California

ANSWER—The patient's skin may be older than the rest of his organs, beginning atrophy with lessening circulation and failing production of oil rendering it hypersensitive. A careful examination for liver dysfunction, abdominal tumors, enlarged prostate and diabetes is in order, if not already made. Too frequent bathing in hot water with too much soap is a common cause of pruritus, drying the skin and sensitizing it. Baths should be tepid, of short duration and infrequent. Soap should be used only on the feet and hands and the folds of the body. Oatmeal or bran water, made by boiling the cereal in a gauze bag for five minutes, allowing the water to cool, then squeezing the bag, or using it as a wash cloth should suffice for the rest of the body. Three cupfuls of oatmeal are sufficient for a full bath. After the bath the skin should be dabbed partly dry and an oil or ointment applied at once. Liquid petrolatum or ointment of rose water may be used, or calamine liniment, consisting of calamine powder and zinc oxide, six parts of each, with olive oil and lime water, forty-five parts of each, may be used. One per cent of menthol or 2 per cent camphormenthol may be added, if agreeable. Phenol had best be avoided in application to the whole body.

If these measures do not afford relief, the patient must be satisfied with water baths only for the face, hands, feet and body folds, using oil on the rest of the body.

## TREATMENT OF MYOPIA

To the Editor—Is there any approved medicinal treatment for progressive myopia? L B BUSMAN M D Omaha

ANSWER—Six or eight years ago Meyer Wiener of St. Louis proposed the use of epinephrine hydrochloride 1 1,000 solution, instilled into the eye three times daily to arrest the progress of myopia in younger persons. The idea was on a purely empirical basis, but there have been several reports indicating that at least partial success attends the use of this drug.

More recently, Bothman has suggested that progressive myopia is due to hypothyroidism and advocated the use of thyroid extract for the purpose of arresting the progress of myopia. The reports from various clinics indicate that the theory is entirely unsound and that the myopia is entirely unaffected by the administration of thyroid extract.

There is no other medicinal treatment of myopia now in use.

## MEDICAL TREATMENT OF GALLBLADDER CONDITIONS

To the Editor—During these times of financial distress a large number of my patients with chronic gallbladder disease are refusing operation and demanding medical treatment. Of course surgery is not advisable in many cases. What kind of a medical regimen will make these patients more comfortable and reduce the frequency of exacerbations of the condition? Are methenamine and sodium succinate considered of value? What are their indications? Please omit name.

M D Illinois

ANSWER—Many patients suffering from gallbladder conditions do not require surgical treatment. This applies particularly to those who have no calculi and in whom cholecystographic examination reveals either a poorly concentrating gallbladder or one that concentrates fairly well but shows some delay in emptying after the fat meal.

If calculi are present it may not make any difference what diet the patients are following, because they may feel perfectly well between attacks of colic irrespective of what they eat. If, however, they have discomfort, the diet will be the same as for those with simple cholecystitis. The food should be nonirritating and of the kind that can pass through the pylorus readily. Therefore it should be either fairly well comminuted or thoroughly masticated. All raw vegetables and raw fruits and cooked vegetables like cabbage and celery should be avoided. Likewise spices, condiments dressings with mustard graves, the hot sauces so frequently in use, smoked and spiced meats and fish, bran and whole wheat bread, clear bouillons and strong alcoholic beverages should be eliminated from the diet. The food need not, however, be entirely tasteless. For a while it was customary to keep the fats in the diet low. This is not necessary. Many patients are able to ingest fats with impunity because they stimulate the gallbladder to contract, and unless there is a high grade spasm this effect is desired. Most of the fruit juices, such as orange, grape or pineapple are generally well tolerated. It is advisable that

the patients avoid large meals. If there is much discomfort the meals should be as much as possible of equal size, preferably small in amount and supplemented by some food at 10 a. m. and about 3 30 p. m. Attention might be called to the fact that in the days before the x-rays were in common use for diagnosis many patients with gallbladder disease, wrongly diagnosed as having peptic ulcer, fared well on a milk and cream diet. This is an example of what repeated small meals will effect. Tincture of belladonna in 1 cc doses before or after meals is frequently of value and rhubarb and soda mixture, 75 cc after meals will relieve postprandial distress in most cases. It is not necessary at this time to prescribe any ordered diets, because the observance of the precautions mentioned will suffice. There are no particular indications for the use of the drugs mentioned in the question.

## HYPERSECRETION OF SEBACEOUS GLANDS

To the Editor—Can you outline a course of treatment for a young man a college student who complains of a hypersecretion of the sebaceous glands of the nose and forehead? Astringents and ultra violet radiation have but a temporary corrective effect. This condition is quite embarrassing to him as it is very noticeable. Please omit name.

M D Pennsylvania

ANSWER—Hypersecretion of the sebaceous glands is a more or less normal condition during the age of adolescence. The majority of local applications have only a temporary effect. In selected cases the cautious use of x-rays, one-eighth skin unit, unfiltered, once a week, may be of considerable service. The skin should be inspected carefully every week for evidence of dryness or wrinkling and as soon as improvement sets in the treatment should be discontinued. From eight to twelve exposures should constitute a maximum, as the sebaceous glands vary in their susceptibility to x-rays. In lieu of x-rays the frequent use of soap and water should be insisted on and at night a half strength lotio alba may be applied. The following formula has recently been suggested:

Solution of sulphurated lime (N F) filtered	30 cc
Saturated (1½ 1) solution of zinc sulphate in rose water (filtered)	20 cc
Glycerin	5 cc

The diet should be low in fats and carbohydrates.

## VARICELLA PUSTULOSA

To the Editor—An infant, aged 10 months has been sick about two weeks. Illness began with chickenpox following contact with children who had the condition in a home where the infant was staying. Following the attack of chickenpox a cold and pneumonia developed. A greasy cloth containing turpentine and lard was applied over the chest, following which application the ulcers developed. The places where the eruption first appeared developed into ulcers all over the chest and abdomen, also some developed on the back and in the groin. The ulcers are rounded, are very deep and exude a mucopurulent substance with a very offensive odor. The entire scalp is a solid mass of small ulcers over which had been spread an ointment the composition of which I do not know. There are a number of tiny ulcers and spots where the original eruption began. I first examined the child April 6 1934 at about 11 30 p. m. The pulse was 162, respiration 54 and temperature in the axilla 103 F. The lungs and bronchial tubes on auscultation showed moist rales, and a percussion area of dullness over the bronchial tubes and lungs. The child was well nourished up to the attack well developed and with no lack of bony development. The parietal and occipital fontanels are closed. The symptoms mentioned together with ulcers covering the head, chest, abdomen and back were the principal ones. My diagnosis was bronchial pneumonia. The condition that is puzzling is the ulcers. The mother's and father's blood Wassermann and Kahn reactions are negative. Tests are negative for tularemia and undulant fever. Evidently the ulcers are not caused by the application to the chest as they are over the head and back. Any information or opinion will be appreciated.

W F BODDIE M D, Forsyth, Ga

ANSWER—In the literature one will find cases recorded in which most of the chickenpox eruptions become furuncles or solitary abscesses. This condition is spoken of as varicella pustulosa. These multiple purulent lesions occur mostly in poorly nourished children or in those whose resistance has been lowered by previous illness, or sometimes in patients in whom the skin has been irritated. One author cites a case in which varicella pustulosa occurred after an irritating mustard bath. Urine and feces may irritate the eruptions, which occur in the gluteal and inguinal regions and transform the varicella eruptions into solitary abscesses. Cases of general pustulation often suggest smallpox particularly when the condition occurs in adults. Varicella pustulosa must be differentiated from the gangrenous type of the disease, which closely resembles it. In the gangrenous type the ulceration takes place not only beneath the scab but also peripherally, with the formation of a grayish or black slough. The lesions may become confluent and form ulcers of considerable size. Rolleston points out that in the

worst cases the disease involves the whole thickness of the skin and even the muscle. In some of the gangrenous cases it is reported that virulent diphtheria bacilli have been found in the lesions, although the administration of antitoxin did not avert a fatal issue.

In cases in which the varicella lesions undergo suppuration, numerous complications may occur. The most severe is a general septic infection, usually with high fever and associated with a severe and fatal course, or bronchopneumonia may occur, with a similar result.

The treatment of varicella pustulosa should consist of aseptic care of the individual lesions, and frequent cleansing with boric acid solutions or some mild antiseptic, or the patient may be immersed in a warm bath. The addition of potassium permanganate to the bath water has been recommended. The child should be bathed in such a solution once or twice daily and should be allowed to remain in the bath ten or fifteen minutes, or at least as long as he remains comfortable in it.

On account of the exhausting and debilitating effects of this diffuse suppurative process, every attention should be given to the nourishment and general hygiene of the child and to such supporting measures as may be indicated.

#### DOWELL TEST OF PREGNANCY

*To the Editor*—In an abstract of an article written by Donald M. Dowell in the *Journal of the Missouri State Medical Association* (July 1933 p 275), there was mentioned a new test for pregnancy. This test consisted of the intradermal injection of anterior pituitary extract. Is this test accurate? If so, can any anterior pituitary extract be used? Please omit name.

M D, Pennsylvania

**ANSWER**—Dowell attempted to detect pregnancy by injecting an "extract of anterior pituitary gland" intradermally into the flexor surface of the arm of pregnant women, but no reactions were observed. However, when he injected a few minims intradermally into the flexor surface of the arms of nonpregnant women he obtained a marked degree of erythema about the wheal at the injected site. Dowell believes that this may be a new phase of allergy. He reasons that possibly a patient who is elaborating a principle identical with that in the extract employed may have developed a tolerance for this particular substance. A patient who is not doing this would show a reaction when this substance is injected intradermally. It is not clear from Dowell's report whether the test substance is actually an extract of the hypophysis itself or whether, as appears more likely, it consists of the "anterior pituitary-like" gonadotropic factor from the urine of pregnancy. No data are given as to how soon after injection the erythema may be expected to occur or how early in pregnancy the reaction fails to appear. Recent work by Collip and his associates indicates that it is possible to develop in animals an "antihormone" against the hypophyseal-like gonadotropic factor of the urine of pregnant women.

Dowell does not give any statistics but simply says "This test has been accurate in the author's hands and in others. It is simple, safe and quite inexpensive."

It is to be hoped that Dowell will state his method more accurately so that others will be enabled to try out the test to see whether it is dependable.

#### IODIDES IN SYPHILIS

*To the Editor*—Quoting from your reply of January 5 as to the treatment of Wassermann fast syphilis: "The iodides should not be omitted." What is considered a course of iodides in syphilis? I am giving lipiodine (Ciba) for arteriosclerosis one tablet daily. How long should I continue it? Could I use the latter product in Wassermann fast syphilis?

J H Boyd M D, Trenton Mich

**ANSWER**—An iodide does not exert antiseptic action against *Spirochaeta pallida* or increase specific cellular resistance, it is merely an adjunct to treatment chiefly for the purpose of assisting in the resolution of granulomatous tissue. One therefore can hardly speak of a definite course of iodides. They are generally given in doses of from 1 to several grams three times daily until the desired effect has been obtained, as evidenced by the relief of symptoms, such as pains, and then continued in smaller dosage for months or even years with the hope that this may prevent the formation of granulomas. No form of iodide has any definite influence on the Wassermann reaction itself. Its use in Wassermann-fast syphilis is merely desirable for the reasons stated. In the treatment of arteriosclerosis, the use as well as the value of iodide is entirely a matter of opinion and no rule can be formulated regarding the length of the course.

#### STAMMERING

*To the Editor*—A boy aged 9 years whose birth was normal at term and who has always been well and healthy except for measles, chickenpox and whooping cough is a little mentally slow but not to an abnormal degree. He is normal in his reactions. He attends a private school where he is in the fourth grade. His work is up to the average and his intelligence quotient is normal. His father is of somewhat nervous temperament and was afflicted with stammering as a young man and still has some impediment in his speech at times. All other history is negative. The boy was a little slow in beginning to talk and even at the present time retains to a certain extent baby talk. He stammers intermittently; that is, there has always been a slight defect, though at considerable intervals it almost entirely disappears and then for no reason reappears. At present he is in one of these occurrences and has a great deal of difficulty in speaking l and r. This is not so much a repetition of the letter as it is a difficulty in getting it out and a tendency to repeat the whole word. Of course, this condition is much worse when he is excited or angry. He does not seem to show any evidence of the so-called nervous disposition, he eats well, he sleeps well and he has all the desires and activities of a normal boy. He has been circumcized. I will appreciate any advice you can give me as to the best method of procedure as to the correction of this type of trouble. Please omit name.

M D Wisconsin

**ANSWER**—Three or four things can be done to cure this case:

1 The parents of the child should see a neurologist trained to specialize in speech disorders.

2 Some of the many books on the treatment of stammering should be consulted.

3 The child should be placed in a good speech class in the public schools.

4 A case of stammering needs constant attention. Treatment has to be changed according to the way the patient responds. These ways vary from case to case and cannot be foretold. The best method is one that builds up concentration and after that the control areas of speech.

#### ANEMIA OF PREGNANCY

*To the Editor*—I have a patient who is about two and a half months pregnant. She complains of excessive gastric secretion which comes up into her mouth as a thick slimy mucus. This is annoying in the extreme because she either vomits or regurgitates nearly all her food or oral medicine which is diluted with this material. Urinary examination is negative for albumin casts, sugar, indican and acetone. The specific gravity of the urine is 1.028. No ammonia or urea nitrogen tests have been made. The systolic blood pressure is 120 diastolic 90. The Wassermann reaction is negative. Blood smears show juveniles 3, segmented forms 4, eosinophils 5, large lymphocytes 7, small lymphocytes 41 per cent. The red cells are normal in size and shape and there is no pathologic condition of the white cells other than with the eosinophils. There is a slight achromia. The red blood cell count is 2,500,000. I take it that she is suffering from the chlorotic anemia of pregnancy. Am I correct in this presumption? Since the patient cannot tolerate medicine on her stomach, what is the most effective method of administering iron? By injection? What products do you recommend in this respect? Is liver extract concentrate of any value in this case? Will this condition spontaneously cease after the three months' reflex period is over and her stomach condition clears up enough for oral administering of iron then, or is it necessary to get the red cells to normal before this condition will cease? If the condition seriously interferes with the patient's nutrition after the three months, would you consider terminating pregnancy?

M A Thomas M D, Alto Ga

**ANSWER**—There are essentially two types of anemia, the secondary or hypochromic form and the pernicious or hyperchromic form. In the latter the blood changes are characterized by diminution in the red count, a high color index, variation in shape and size of the red cells, often regeneration signs, polychromatic red cells and basophilic stippling, moderate leukopenia with a relative increase in the lymphocytes, and a diminished number of blood platelets. Gastric anacidity is the rule. In chlorotic and secondary anemia there is a low color index but the cells are essentially normal. About half of the women who have a secondary anemia during pregnancy have a pronounced hypochlorhydria, which returns to normal after delivery. In most instances there is a progressive increase in the anemia during pregnancy. According to Strauss and Castle (*Am J M Sc* 185:539 [April 1933]) the hypochromic anemia of pregnancy is due either to a direct dietary insufficiency or to a deficiency conditioned by gastric anacidity, hypoacidity or associated defects in the presence of the fetal demand for blood-building material. This type of anemia may be completely relieved either during or after gestation by the administration of iron in large doses. R D Mussey (*Journal-Lancet* 52:643 [Nov 1] 1932) is convinced that the use of ferric citrate or ferric ammonium citrate together with a balanced diet high in vitamins and the addition of vitamin D in the form of concentrated viosterol is of distinct value in treating the secondary

anemia of pregnancy. There is rarely any need of interrupting the gestation except in the cases of pernicious anemia. In practically all cases of secondary anemia, in which the red blood cell count and the hemoglobin decrease markedly, single or repeated blood transfusions are nearly always curative and will avoid the necessity of terminating pregnancy. Liver extract is not as helpful in the cases of secondary anemia as in the cases of pernicious anemia. In the case cited the gastric distress will most likely soon abate, so that iron preparations and a proper diet can be administered to the patient. If not, a blood transfusion should be given, especially if the red blood cells decrease in number.

The patient should be advised to be outdoors in the fresh air and sunlight (if available) as much as possible. The diet should contain abundant animal food, beef, mutton and chicken, and the meals should be small and often repeated. When iron is prescribed, the inorganic is as useful as the organic form. Among the inorganic forms are the tincture of ferric chloride, the reduced iron in tablet or capsule form, the pills of ferrous carbonate and saccharated ferric oxide. Preparations of iron that may be administered hypodermically are iron cacodylate, iron arsenite, and iron citrate. In many cases arsenic is of great help. This may be administered by mouth in the form of solution of potassium arsenite or intramuscularly as sodium cacodylate.

#### SYPHILIS IN PREGNANCY

To the Editor—An untreated secondary syphilis is discovered in a primipara during the first two months of pregnancy. Is a therapeutic abortion justifiable from the medical standpoint? If a therapeutic abortion is not done, what are the chances of the child contracting syphilis assuming that the mother has the best attainable treatment during pregnancy? Please omit name.

M D Illinois

ANSWER—In view of satisfactory results achieved with modern treatment, therapeutic abortion need not be considered in cases of acute secondary syphilis of the mother in early pregnancy. Treatment should begin as early in pregnancy as possible, must be energetic and systematic, and should be continued until term. The chances of the fetus contracting syphilis in spite of thorough and persistent treatment are few, but careful observation of the infant and periodic serologic tests are advised.

For a comprehensive description of syphilis in relation to pregnancy, the correspondent is referred to Gellhorn's chapter on "Syphilis in Women" in the second volume of Curtis's *Obstetrics and Gynecology* (Philadelphia, W. B. Saunders Company, 1933).

#### FILTRATE TREATMENT OF TRICHOMONAS VAGINALIS

To the Editor—Please let me have some information concerning the filtrate treatment of trichomonas vaginalis as referred to in an article by W. A. Thomas and E. R. McCarthy in *THE JOURNAL* March 10 page 766. Please omit name.

M D Virginia

ANSWER—Trichomonas is practically always found in association with a streptococcus in cases in which symptoms are severe. On disappearance of the streptococcus, Trichomonas either disappears or ceases to cause symptoms. The streptococcus is isolated from the vaginal material, usually on brain broth, and then transplanted to blood agar plates, and flasks of dextrose broth are inoculated from these. Theoretically this broth should be filtered through a fairly fine Berkefeld filter after forty-eight hours, reinoculated, and this process repeated until no further growth takes place, that is, until the culture medium is "exhausted"—not from utilization of the content, but because of the production of a toxin or antiviral.

Results about as good are obtained by allowing the broth to stand, with occasional shaking until it clears, that is, until the upper portion becomes perfectly clear and the sediment has settled to the bottom. No further reinoculation will produce growth. This is filtered through a Berkefeld filter and is sterile. The chief difficulty in clinical use is to prevent contamination with yeast and the like. It is well to divide the filtrate into small flasks, perhaps 50 cc in each which is enough for individual treatments. The filtrates are preferably autogenous, though good results are reported with pooled or foreign preparations.

In treatment, the vagina is thoroughly cleansed, particular care being taken to remove mucus from the folds, and packs or tampons saturated with filtrate are inserted to remain from eight to sixteen hours. Relief may be almost immediate. Failure may be attributed to impure culture since *B. coli* rapidly outgrows the streptococcus and suppresses its specific growth product, or to failure to obtain the particular strepto-

coccus. However, results are not perfect, and poor results are sometimes seen when the greatest care has been taken in preparation of the filtrate. Treatment may be repeated daily or twice weekly, up to a total of twelve or fifteen times if necessary. Besredka, in his monograph *Specific Immunity by Wet Dressings*, explains in detail the theoretical mechanism of filtrates.

#### TECHNIC OF UREA CLEARANCE TEST

To the Editor—Is the urea clearance test the same as described on page 328 volume 2 of *Tice's Practice of Medicine*? The patient is given 30 grams urea dissolved in 4 to 6 ounces of water, and the urine examined for urea by any of the reliable quantitative methods. Please omit name.

M D Ohio

ANSWER—The technic of the blood urea clearance test is the following. The test is preferably performed during the morning hours. The previous meal should be a moderate one without tea or coffee. The patient is given a glass of water at the beginning of the test and remains quiet while the urine is collected for two periods of one hour each, and the volume of each specimen is measured. Blood for a blood urea determination is drawn a few minutes before the end of the first hour period. The following determinations are made:

U = urea concentration in urine (milligrams of urea nitrogen per hundred cubic centimeters)

V = urine volume (cubic centimeters per minute)

B = urea concentration in blood (milligrams of urea nitrogen per hundred cubic centimeters)

Cm = volume of blood freed from urea per minute, being for a normal adult of average size about 75 cc. of blood per minute.

The calculation is  $Cm = \frac{UV}{B}$

When the urine volume is less than 2 cc per minute, the volume of blood averages about 54 cc of blood per minute.

Then  $Cm = \frac{UV}{B}$

Results are expressed in terms of cubic centimeters of blood cleared of urea per minute or in terms of percentage of average normal clearance.

This test is one of the most sensitive methods for determining renal insufficiency. For complete details consult "Urine and Urinalysis" by Gershenfeld, Philadelphia, Lea & Febiger, 1933, pages 237 to 240.

Urea is given by mouth in urea concentration tests, not in the clearance tests. In the urea concentration test the amount of urea in the blood or urine or both is afterward determined. For these tests see the work of Bowen in the *American Journal of the Medical Sciences* (174 769 [Dec] 1927).

#### FRAUDULENT FEVERS

To the Editor—Frequently I have to determine the question of active or inactive pulmonary tuberculosis. Occasionally a patient will have a low grade fever of 99.2 or up to 99.6 and even 100, in whom all the other signs, physical and x-ray indicate an inactive or arrested state. Usually on certification of the temperature by the nurse the temperature will prove to be normal. However, once in a while I find one in whom even certification does not show a normal temperature. Perhaps, then, if the temperature is taken at irregular intervals the result will be a normal reading. Naturally, the suspicion is that the claimant is some way or other producing a fraudulent temperature. I am unable to detect the means that this fraudulent fever is produced. Therefore I am writing to inquire what the various methods are that malingerers might use to bring about these false readings.

M D, Arizona

ANSWER—Perhaps the most common method used to produce fraudulent temperature readings is taking cold or hot water by mouth. In sanatoriums there is the occasional patient who desires to be discharged but whose temperature is sufficiently elevated to cause the medical director to refuse to recommend any exercise. If the nurses take temperature readings and such patients know about the time the readings are to be recorded, they either go to the washroom or have a glass of cold water brought by another patient. They not only drink some of this but also retain some in the mouth until just before the thermometer is introduced. Other patients who desire to have a false elevated temperature recorded use hot water. Holding the thermometer on a hot water bottle has been used by some malingerers to produce false temperature readings. Rectal temperature readings will usually overcome the possibility of such malingerers. There are drugs, such as cocaine, that will produce elevation of temperature, but the dosage required is so large that other symptoms which the drugs produce would be easily

detected. Good evidence has accrued to show that the red cell sedimentation test and the differential neutrophil count are delicate indicators of the activity of a tuberculous process. These examinations are especially valuable in the group of questionable cases.

#### WELDER'S CONJUNCTIVITIS

*To the Editor*—In my industrial work I have had several cases of welder's conjunctivitis to deal with in men using acetylene and electric torches. The color of the glasses used in this welding has included brown light amber, blue green, olive green and blue. What I should like to know is whether there is any color of the lens best suited to protect the eyes in acetylene and electric welding. Besides the density and opacity of the lens, does the color have any particular significance in this work?

A J HERTZOG, MD New Orleans

**ANSWER**—In procuring protection of the eyes of welders it is necessary to utilize types of glass that serve as barriers to ultraviolet, infra-red and luminous light rays. Glass may be procured with little or no color which absorbs a high percentage of ultraviolet and infra-red rays. Such glass is ordinarily unsuited for welding because of excessive amounts of luminous rays that may be transmitted. Color is therefore desirable for the lowering of the visible light transmitted, but in addition color itself contributes to the barring of the ultraviolet and infra-red rays. At the present time various shades of olive green are accepted as representing the best color for welding work. Dark calobar glass is of such color and chemical construction as to transmit 35 per cent of the luminous rays but to bar 92 per cent of the infra-red and 100 per cent of the ultraviolet rays. Possible variations in color density meet every requirement of the several forms of welding work.

#### SERUM IN UNDULANT FEVER

*To the Editor*—I should like to ask your opinion concerning Dr O'Neil's immune serum for use in undulant fever cases. This was mentioned in an article on the subject by Beattie and Rice (*THE JOURNAL*, May 19 p 1670). I would appreciate information as to where it may be obtained, how best it is employed and whether it would be worth trying in a mild case of nine months duration in which only symptomatic treatment has been given. I do not have access to the *Ohio State Medical Journal* to which the footnote referred. Please omit name.

MD Sperryville, Va

**ANSWER**—The antiabortus serum developed by A E O'Neil may be obtained without charge for clinical trial by addressing him at the Department of Bacteriology, Cincinnati General Hospital, Cincinnati. The best results have been obtained by administering a total of 60 cc of the goat antiserum in three consecutive daily doses of 20 cc each, intravenously. Experience thus far has shown that but few patients receive much benefit from serum therapy after the fifth month of illness. It is doubtful whether serum would induce any appreciable improvement in a patient who has been ill for nine months, even if the infection is mild. The optimal time for serum therapy is before the end of the fourth month of illness.

#### MUSCLE CRAMPS DURING SLEEP

*To the Editor*—Please inform me as to what may be the probable causes of tonic spasms in one or more toes occurring only during sleep in an otherwise apparently healthy young adult woman. The patient is subject to cramps in her feet while swimming in cold water. She also grinds her teeth during sleep. Please omit name.

MD New York

**ANSWER**—Muscle cramps such as are described by the correspondent are common and ordinarily do not indicate disease of the neuromuscular or vascular systems. Hunter (*Internat Clin* 4 109-110 [Dec] 1932) gives an excellent description. "Half awake in the morning, one lazily stretches out and is suddenly seized in one calf with a very painful cramp which lasts about a minute, during which the tendo achillis is powerfully contracted drawing the fore part of the foot downward." The mechanism of these cramps has been presented by Marx (*California & West Med* 38 96-97 [Feb] 1933). "Muscle cramps are usually brought on by sudden exaggerated or wrongly directed impulses when a muscle action does not meet the anticipated amount of resistance or is not checked by the controlling antagonistic muscles, as is normally the case. After producing a maximum contraction the superfluous amount of muscle energy liberated by the disproportionate impulse is converted into a muscular spasm."

Muscle cramps occurring during sleep appear to arise in the same manner as do those which follow stretching except that the primary muscle contraction is an involuntary or sleep move-

ment in the former instance and voluntary in the latter instance. In swimming, the inhibiting effect of the cold on the peripheral circulation contributes to the disposition to cramps, probably by interference with the normal metabolism of muscle.

The treatment during the episode is the forced manual extension of the muscle involved by the cramp. If, for example, the muscles of the calf are involved, the foot should be forcibly dorsiflexed. Prevention of the episodes is usually simple avoidance of unopposed muscular contraction as during stretching and of swimming in cold water by those having a predisposition to cramps. Individuals who suffer during the sleeping hours should be fitted with a special shoe or boot to prevent involuntary muscle contraction. If the aforementioned plan of treatment is unsuccessful, the administration of some of the acid forming salts, as ammonium nitrate, at bedtime may be helpful. The assumption is that the salt prevents the tendency to alkalosis, to which the neuromuscular mechanism is unduly sensitive.

#### DYSMENORRHEA

*To the Editor*—Can you send me advice as to how to treat a case of severe dysmenorrhea? The patient has been suffering since puberty going to bed the first day of each period because of agonizing cramp-like pain. The pain is usually confined to the first few hours before the flow is established. Medication required has always been strong nothing giving relief except narcotics which have been used sparingly to avoid habit formation. When the flow does start she states that there are always many clots and pain subsides. Examination confirmed by an eminent gynecologist reveals no abnormality. About two years ago another physician performed a dilation and curettage but the symptoms were unchanged. The patient is now 26 she has been married seven years and has no children. No contraceptive methods were ever used. The sex act is apparently normal. The spermatozoa of the husband are of normal motility even several hours after ejaculation. I do not know the cause of the sterility. The patient's general health is fine and her past history negative. The menses are regular (from twenty-eight to thirty days) and last four or five days and the number of napkins used is normal. There are often flushes and breast pains preceding the periods but these are not severely discomforting. While the patient has no other complaints I believe that she has a slight tendency to hyperthyroidism and there is a mild pituitary type of girdle obesity. This was not noticed by previous physicians and was dismissed by the gynecologist as inconsequential so I may be exaggerating. Could a glandular derangement account for all the disturbances? Could such severe pain be due to endocrines? What causes the clots each month? Could it be abortions? My problem consists of the dysmenorrhea, sterility, mild endocrine disturbance of the thyroid and possibly pituitary. I am most anxious for your advice as to treatment. Please omit name.

MD New York

**ANSWER**—Dysmenorrhea is one of the most baffling problems with which physicians have to deal in gynecology. Based on physiologic investigations by Reynolds, Emil Novak (*Am J Obst & Gynec* 24 319 [Sept] 1932) comes to the conclusion that the immediate cause of dysmenorrhea is an exaggerated contractility of the uterus manifested by pain if the pain threshold is lowered or if there is an actual imbalance between the two hormones that appear to regulate this. These two hormones are the follicular factor, the normal stimulant of uterine excitability, and progesterin, the normal inhibitor. Hence in cases of dysmenorrhea it is advisable to administer biologic uterine antispasmodics and the one recommended by Novak is the luteinizing principle obtained from the urine of pregnant women. This substance, by stimulating the production of progesterin, tends to inhibit the rhythmic contractility of the uterine musculature. In some cases atropine sulphate administered for twenty-four hours before the flow of blood begins is helpful. Of course, rest, hot applications and analgesics should also be prescribed during the attack of pain. In extreme cases, and only when everything else has been tried, it may be advisable to perform the operation known as pelvic sympathectomy described by Greenhill and Schmitz (*THE JOURNAL*, July 1, 1933, p 26). The clots in this case do not indicate abortions although, to be absolutely certain, the tissue passed should be carefully studied and any pieces that look like ovular products should be subjected to microscopic examination. The clots in this case are almost certainly brought about by coagulation of the blood due most likely to a deficiency in the ferments that normally prevent clotting of blood in the uterine cavity.

Sterility is another problem that frequently baffles gynecologists especially when the examination of both husband and wife fails to reveal any abnormalities. Since there is a question of hyperthyroidism, it is well to have a basal metabolism test made. Empirically, small doses of thyroid may be given because occasionally it yields good results. No mention is made of a Rubin tubal patency test or of a Huhner test. These should be made. Pregnancy not infrequently follows the performance of a Rubin test.

APPARATUS FOR DETERMINATION OF BASAL  
METABOLISM

To the Editor—I am interested in purchasing a basal metabolism machine and should like to know whether you consider a machine with the motor blower forced circulation of oxygen more desirable than a machine with the natural circulation of oxygen. Any information you can give me on this subject will be greatly appreciated.

M D, Fla

ANSWER—The Benedict type of metabolism apparatus (closed circuit) originally required some means of impelling the air through a series of absorbers and their numerous connections. The apparatus of this type as now constructed and in general use lends itself admirably to the adaptation of valves and the discard of any mechanical air impelling device. The use of valves together with a properly balanced spirometer bell, in a properly conditioned apparatus, allows easy and normal breathing and insures basal results.

The positive or negative pressure maintained throughout the circuit invites leaks, especially in the region of the mouth and the nose.

The use of the impeller rather tends to encourage neglect in the proper care of the apparatus by promoting a false feeling of security in the mind of the operator, while it is of doubtful assistance to the respiration of the subject. In fact, too fine too much or impacted soda lime, too much resistance due to too long tubings, an improperly balanced spirometer bell and kinks or obstructions by accumulation of moisture may all be responsible for a partial or even a complete obstruction somewhere in the ventilation circuit. All this may take place during the test without any immediate apparent sign of trouble, though the motor keeps humming along as usual while the spirometer bell is rising and falling without interference and air continues to be available through the mouthpiece. In the absence of the valves, the air in the entire system can move in one direction or the other even with a complete obstruction, in which case the subject is merely rebreathing part or all of his expired air.

## GAG REFLEX IN TONSILLECTOMY

To the Editor—Can you tell me the best way to control the gag reflex in doing tonsillectomies? I have used weak solutions of cocaine or butyn to paint the pillars, palate and uvula with fair results. A dentist said he had heard of some tablet which the patient swallowed to control the gagging. Please omit name.

M D, Minnesota

ANSWER—Tablets containing a small amount of orthoform or ethylamino benzoate placed on and allowed to dissolve on the base of the tongue will at times lessen the pharyngeal reflex. If the patient is instructed to gargle with ice cold water several times a day for several days prior to the operation, and if in the operating room pieces of ice are held on the posterior third of the tongue and allowed to melt, the reflex also will be considerably diminished. With many individuals, if these procedures have been carried out, and the patient instructed to breathe very deeply with the mouth wide open, and with special emphasis on the deep inspirations, the gagging will usually be greatly lessened. Preoperative medication with from 0.2 to 0.4 Gm of one of the barbituric acid derivatives is of considerable value.

While it is true that the pharyngeal reflex varies in activity within a rather wide normal range, the psychologic attitude of the patient and the proper instructions of the surgeon will usually lessen the excessive excitability of some pharynxes sufficiently to enable tonsillectomy to be performed with comfort under local anesthesia.

## IRON IN ANEMIA

To the Editor—In the Year Book of General Medicine 1933 Drs. Minot and Castle's editorial note on page 364 is: A simple 50 per cent aqueous solution of iron ammonium citrate judiciously used in oral doses of from 2 to 6 grams daily. Could you please express the thought which Drs. Minot and Castle wish to convey with the judicious use of iron? 1. What are the contraindications to the use of iron therapy? 2. Is there any harmful effect of the preparation on the teeth? 3. What is the dose for children from 2 to 4 years old of this preparation? 4. How well do both adults and children tolerate these large doses of iron ammonium citrate? Please omit name.

M D, New York

ANSWER—Undoubtedly the thought which Drs. Minot and Castle wish to convey by the use of the word judicious is that iron and ammonium citrate in 50 per cent aqueous solution should be used first for patients who may be expected to benefit from it and secondly administered in such a manner as not to cause undesirable symptoms.

1. There are no contraindications to the use of oral iron therapy except in patients who will not be benefited, and in

patients with irritative lesions of the intestinal tract when distinct discomfort ensues on careful trial.

2. Iron and ammonium citrate has little, if any, harmful effect on the teeth.

3. The dose of iron and ammonium citrate for children from 2 to 4 years of age is in the vicinity of 1 to 2 Gm daily.

4. Adults and children usually tolerate well these appropriate doses of iron and ammonium citrate, provided the medicine is administered at first in small doses and the maximum dosage attained in a period of from three to four days.

The administration of the material after meals is also desirable, in order to avoid gastric irritation. The most common undesirable symptoms are discomfort referable to the intestine or diarrhea, which can be obviated in most cases by the precautions just described. Rarely, individuals are found who cannot tolerate large doses of iron and ammonium citrate because of diarrhea. In such patients it is worth while to try other preparations of iron. The dosage should be chosen to yield a similar content of atomic iron.

On the other hand in many patients little effect is obtained by using small doses of iron, in contrast to the beneficial effects of the so-called large dosage now commonly employed.

## POSTMORTEM INJECTION OF LYMPHATICS

To the Editor—I am anxious to obtain some data on the method of injecting the lymphatics of the terminal ileum and cecum post mortem. Any information or reference to the subject will be appreciated. Please omit name and address.

M D, New Jersey

ANSWER—The best method for injection post mortem of the lymphatics of the cecum and ileum is still that of Gerota (*Anatomischer Anzeiger* 12 216, 1896).

Select if possible a young cadaver (fetus or infant) with the cecum empty. Note from textbooks the position of the lymph plexuses spread out like mats of ivy vines in three layers: (1) subserous, (2) submucous, (3) mucous. Inject with glass cannulas drawn out in a flame to fine tubular points, from 1 to 1.5 cm long. Use a 10 cc syringe. Insert the glass needle along the plane of the plexus of lymph capillaries, thus cutting through some of the capillaries. Then withdraw the needle a little so as to allow the fluid to run into the open ends of the cut capillaries. Inject very slowly, with but little pressure. The whole apparatus must be absolutely clean.

For injection fluid use prussian blue (oil color in tubes, obtainable at art shops), 2 parts, pure turpentine, 3 parts. Rub up thoroughly in a porcelain mortar. Add sulphuric ether, 15 parts, and triturate in a mortar till the consistency is uniform. Filter through a double layer of fine linen. Preserve in a glass stoppered bottle.

This suspension works much better when fresh, so it is advised to make up only a little for immediate use.

## BONE GRAFT AFTER INJURY TO ULNA

To the Editor—A white youth aged 18 American supposedly fractured both bones of the right forearm three years ago at the junction of the lower and upper two thirds. One and one-half years following the accident he first noticed some weakness of his right hand while milking cows. The weakness has gradually increased and is quite noticeable at the present time. Examination reveals a definite shortening of the ulna—about three fourths inch—with increased mobility of the hand to that side. The bones are straight. The roentgenogram reveals a definite shortening of the ulna—atrophy of the distal end with no evidence of infection. Will you please outline the treatment of this case for me? If a bone graft is indicated, when should it be done? Please omit name.

M D, Wyoming

ANSWER—The treatment that holds out the greatest promise is removal of the atrophied distal end of the ulna and substitution of an autogenous graft of bone. Since the ulna is small, one difficulty confronting the surgeon is to find a satisfactory method of uniting a graft with the ulna. A number of methods have been used by different men: chiseling one end of the graft to a point and inserting the pointed end into the medullary cavity overlapping the end of the ulna with the graft and surrounding the overlapped ends with a layer of periosteum obtained at the same time that the graft is obtained, and leaving a cuff of periosteum attached to that end of the graft which is to be placed next to the ulna, laying the graft end to end with the freshened distal surface of the ulna, and suturing the periosteal cuff to the periosteum of the ulna. Although metal wire, screws and metal plates have been utilized to fix the graft to the living bone these methods are gradually being discarded and some one of the methods described, which does not involve the implantation of a foreign substance or material, is greatly to be preferred.

INTERSTITIAL EMPHYSEMA AFTER FRACTURE  
OF RIB

*To the Editor*—Will you please describe the physics or mechanism of interstitial emphysema following rib fracture—this to settle a seemingly never to end argument at our hospital staff meeting. An old man after a crushing injury of the right side of the thorax, in which several ribs were fractured, developed emphysema, which became general over the whole body. He died in four days of pneumonia of the left lung. What we want to know is: How does the air get from the small (in this case) hole in the visceral pleura through the fairly large hole in the thoracic wall? There was no pneumothorax evident in a roentgenogram taken eighteen hours after the injury, when the emphysema had become very extensive.

HUGH WILKINSON, M D, Kansas City, Kan

**ANSWER**—The air constituting an emphysema of the chest wall, in the absence of an opening wound through it, comes from the lung. If the pleurae are adherent, as in the case of an old pleuritis, and the lung is injured from a broken rib, the air passes directly from the lung into the tissue of the chest wall. If the lung is not adherent in the region of the injury and there is a sufficient distance around it so that the lung can collapse somewhat, the air will leak into the pleural space and may pass into the soft tissue of the chest wall when intrapleural pressure is increased during coughing or straining. Several hundred cubic centimeters of air in the pleural cavity may not be discernible in a roentgenogram. This is often observed following the first injection of air in therapeutic pneumothorax.

## NECROSIS OF DISTAL PHALANX OF THUMB

*To the Editor*—I have an unusual case: necrosis of the distal phalanx of the thumb in a young woman the only factor is a possible cause that I can figure out being that she has been working rather extensively for the past year using phosphoric acid. I performed an amputation. There was no bleeding and the bone was denuded and necrosed. All the information I can get on the subject is that phosphoric acid does not have any of the attributes of phosphorus. I would be pleased to have you advise me if you have any information on the subject.

C L Best, M D, Freeport Ill

**ANSWER**—It is impossible to explain the necrosis mentioned on the basis of the facts given. If phosphoric acid was taken into the body it would be promptly changed into a neutral phosphate by becoming combined with the alkalis normally present in the blood serum.

The query does not say anything about the condition of the soft parts surrounding the bone. Death of the distal phalanx of the thumb can result from acute, fulminating infection, vascular disease, Raynaud's disease, nerve injury followed by trauma of the soft parts, perhaps unrecognized because of the loss of sensation, and a number of other conditions.

BAROMETRIC PRESSURE IN METABOLISM  
EXPERIMENTS

*To the Editor*—Kindly let me have a statement as to the exact significance of barometric pressures in metabolism experiments particularly rate determinations. Kindly omit name.

M D, Maryland

**ANSWER**—According to Boyle's law, the volume of a given mass of gas kept at constant temperature is inversely proportional to the pressure on the gas. Since the methods of determining the metabolic rate depend on the measurement of the volume of oxygen consumed by the patient, it is obvious that, if the patient was to consume exactly the same amount or weight of oxygen on two different days, the volume of this amount of oxygen would vary with the atmospheric (barometric) pressures on those days. In order to avoid this variation, all volumes are corrected to standard pressure (760 mm of mercury) as well as temperature (0 C).

## BACTERIOPHAGE IN PELVIC SEPSIS

*To the Editor*—Kindly inform me at your earliest convenience regarding the proper treatment of staphylococcal septicemia proved by repeated blood cultures probably arising from a septic phlebitis of the broad ligament from puerperal sepsis. I would appreciate your opinion regarding the merits of treatment by bacteriophage intravenously. What value does treatment have by transfusions from a donor immunized with vaccine injections prepared from this specific staphylococcus? If available kindly give the prognosis and the percentage of cures as reported in these cases.

W BAIRD STUART M D Carlisle Pa

**ANSWER**—Despite enthusiastic reports, the evidence thus far accumulated does not warrant optimism over the value of the bacteriophage or serum treatment of staphylococcal septicemia of pelvic origin. Blood transfusions are of much value in most of these cases even if there is not a profound anemia. Immunization of the donor would be of doubtful value.

Reliable data on the prognosis in such cases are not available, the outlook is usually serious, but these infections vary enormously in severity.

Pelvic examinations should be avoided, unless required to rule out the possibility of a pointing abscess.

The patient should be allowed to change her position as often as she desires, but she should not be allowed to get out of bed, and movements should be made slowly and cautiously. Avoidance of abdominal distention and limitation of enemas are important factors in the treatment.

## FROZEN PELVIS

*To the Editor*—Paul de Kruif has done it again, with 'Young Doctor Heat' in the April *Ladies Home Journal*. Page 88 thereof discourses on that dreadful condition called frozen pelvis. Please tell me just what and why is a frozen pelvis. I can't find it in Graves Crossen Williams DeLee or my dictionaries. Sometimes a pelvis is seen whose southern regions are a bit frigid but just how much more do they have to be cooled off before they're frozen? Please omit name.

M D Missouri

**ANSWER**—"Frozen pelvis" is a coined phrase for the condition in which a solid mass of induration fills the true pelvis. Some describe this hardened pelvis as one apparently filled with plaster of paris. No pelvic organ can be defined by palpation with the exception of the cervix of the uterus, which is firmly fixed.

This condition with ordinary treatment of rest, and similar measures, usually hospitalizes the patient for a period of four or five months. With heat, as administered by the Elliott method, the most desperate cases show rapid improvement. The indurated mass becomes rapidly softened and absorbed. The uterus becomes freely movable and the fallopian tubes and ovaries are easily defined. This result is usually obtained in from three and a half to six weeks.

## GLAND TUBERCULOSIS

*To the Editor*—I have a patient with a chronic draining cervical sinus. She is 18 years of age. Three years ago she developed swollen cervical glands. About two years ago they were incised and since that time have been constantly draining. She refuses surgical treatment. Will you please inform me as to the best way to handle this case medically? Please omit name and address.

M D, Texas

**ANSWER**—The most probable cause is tuberculosis of the glands. All the specific chronic infections or granulomas should be considered in the differential diagnosis. A number of tests, smears, cultures and perhaps the tuberculin test should be performed in an effort to establish the diagnosis.

Tuberculosis of the lymph glands frequently responds to roentgen treatments under competent hands.

General treatment is most important. It should consist of rest, fresh air, nourishing food, cod liver oil medication as indicated and exposure of the entire body to the sun or a sun lamp.

The prognosis for healing is good.

## CONVULSIONS IN CATS

*To the Editor*—What is the probable etiology and therapy for the so-called running fits in cats? Please omit name and address.

M D Ohio

**ANSWER**—So-called running fits in cats are not recognized as such in veterinary literature. It is true that convulsions in cats, particularly young cats, are common. The paroxysm is usually sudden and the cat becomes greatly excited, the hair on the back and tail is fluffed, and the animal may run about swiftly and cry loudly. If in a room it may climb up the drapery or hide under the furniture. The excitement is continuous until the convulsion subsides.

The cause of such convulsions is the result of improper diet, intestinal parasites or ear mites.

The therapy should be directed toward the removal of the cause. To do this a veterinarian should be consulted.

## TONSILLECTOMY IN ASTHMA

*To the Editor*—Is there any undue risk in doing a tonsillectomy in a girl aged 13 who has and is frequently having attacks of asthma? She is a quite nervous child so I would prefer to use a general anesthetic. With the exception of this general asthmatic condition and tonsil disturbance she is quite normal.

R J STEIN M D Pierz Minn

**ANSWER**—As long as the operation is not performed at the time an asthmatic attack is present, no undue risk is involved. It is often advisable to give the patient a mild sedative before the operation.

### Minnesota April Report

Dr E J Engberg, secretary, Minnesota State Board of  
Medical Examiners, reports the oral, written and practical  
examination held in Minneapolis, April 17-19, 1934 The  
examination covered 12 subjects and included 60 written ques-  
tions An average of 75 per cent was required to pass Thirty-  
nine candidates were examined, all of whom passed Three  
physicians were licensed by reciprocity and 1 physician was  
licensed by endorsement The following schools were repre-  
sented

## Book Notices

**The Chemistry of the Hormones** By Benjamin Harrow Ph.D., Associate Professor of Chemistry The City College College of the City of New York and Carl P. Sherwin D.Sc. M.D. Dr.P.H. on the Staff of St. Vincent's Hospital and French Hospital New York City. Cloth. Price \$2.50. Pp. 227. Baltimore: Williams & Wilkins Company, 1934.

This volume is largely a compilation from the published literature of methods of preparing extracts having physiologic or pharmacologic effects, from various tissues, body fluids and plants. The authors state in their preface that they have attempted to "put together a practical book—a book of use to the laboratory worker who wishes to prepare active hormone fractions or to isolate a chemically pure hormone, and of use to the student who wants a connected account dealing with the chemical characteristics of the hormones, in so far as they are known at present." Were this book a complete and critical summary of the literature in question, laboratory workers might find it a useful work of reference, unfortunately, it falls far short of the authors' aim in this respect. Consultation of original publications remains indispensable. It is a matter of grave concern for the present state of knowledge that the chemical characteristics of the hormones, "so far as they are known at present," can be encompassed in a mere 227 pages of text, of which a considerable portion is devoted to notes on biologic effects.

No doubt many investigators write things that they do not "know", such material presumably would have no place in such a volume as this. Unfortunately there is little evidence that the present authors examined critically the material they chose to include.

The first chapter, on the thyroid, is perhaps the least subject to criticism, no doubt because the chemistry of thyroxine is by now amply understood. The succeeding chapters leave much to be desired. In a discussion of the parathyroid Hanson's contribution is dismissed as "suggestive work" and is even subordinated in sequence to that of Berman, whose publication appeared a year after Hanson's original two communications in 1923 which were followed by three more the next year. Curiously, none of these five references are listed in the bibliography. Is it coincidence that the same peculiar sequence and omission occur in a recent review on this subject? There is now apparently no doubt that Hanson prepared highly active extracts of the parathyroid several years before Collip's comprehensive work in this field.

One is startled to find a section on the synthetic fat intarvin included in the chapter on insulin and to read that "Intarvin has the advantage of being active [sic] when given by mouth." Are the authors under the delusion that this fat is a hormone?

In the chapter on the pituitary hormones, the preliminary summary on the anterior lobe has apparently been copied verbatim (with omission of one or two brief statements) from a recent report of the Council on Pharmacy and Chemistry, yet not only is the section in question not included between quotation marks but reference to the Council's report is not even to be found in the bibliography following this section, though it is included as an anonymous publication following the section on the "female hormones." In the description of the method of Van Dyke and Wallen-Lawrence for preparing a growth-promoting extract of the pituitary, the statement in the original publication, "Y cc of crude stock

are reprecipitated by using 20 grams of anhydrous sodium sulphate per 100 cc of solution," becomes, in the book under review, "Y cc of the crude stock is reprecipitated with 20 grams anhydrous sodium sulfate in 100 cc of water." Whereas the former statement is quantitative with respect to relative amounts of crude extract and precipitating agent, the sentence in the book under review defies comprehension.

In the section on the suprarenal hormones, "stimulation of the vagus center causing slowing of the heart" is given as a clinical application of epinephrine. This is hardly a proper therapeutic use for epinephrine but an undesirable side effect of large dosage that one would try to avoid in patients.

It is in the section on the suprarenal cortex that the authors best exhibit the deficiencies in critical judgment and in knowl-

edge of pertinent literature that characterize the book as a whole. In a footnote the impression is conveyed that the discovery dates back only to 1932 that survival of animals after double suprarenalectomy is due to the presence of accessory tissue. The authors are apparently unacquainted with the fact that this was recognized at least twenty years before that. The average survival period of suprarenalectomized cats as reported by Rogoff and Stewart is stated to be eleven days for male cats and ten days (the actual figure in the original paper is ten and three-fourths days) for nonpregnant female cats. The authors do not mention that one eighth of the animals survived twenty days or longer, of which one lived twenty-nine and three-fourths days and another thirty one and one-half. Yet reports by other workers in which the survival periods did not equal, much less exceed, the maximum period reported by Rogoff are accepted as indicating the use of potent products.

Hartman's salt precipitation method is presented presumably as providing a potent extract, it is not mentioned that Rogoff demonstrated that this method is worthless and that for this reason Hartman himself gave it up.

The authors, who should know better, give full credence to the spectacular accounts presented, not only in scientific journals but also in the lay press, of the remarkable recoveries of patients suffering from Addison's disease, after treatment with the allegedly potent cortical extracts of Hartman and of Swingle and Pfiffner, while they consider unconvincing the conservative and eminently reasonable claims of Rogoff. They report a case of Addison's syndrome in which the patient was "in a state of complete collapse", within thirty-six hours after administration of the Swingle-Pfiffner preparation "a marked effect on appetite and strength was apparent. The patient, who had been so nauseated as to retain water with difficulty, now asked for viennas and sauerkraut and in lieu of the latter ate a double order of beefsteak with relish." While this patient was reported as doing nicely in the first publication on Nov. 7, 1930, and this was repeated as late as the end of December 1930 (the case was again mentioned in another paper the following month), a subsequent report in November 1931 showed that the patient was already dead on Nov. 11, 1930. The authors appear to be unacquainted with the fact that patients with Addison's disease often have spontaneous remissions, sometimes of a spectacular nature.

It is mentioned that Eagle found considerable amounts of choline in extracts prepared by the Swingle-Pfiffner method, a footnote indicates that this is denied by the latter investigators. It is not stated that Cleghorn reported the presence of histamine in such extracts a year before Eagle's paper appeared, nor do the authors appear to be aware of the fact that Hunt noted the presence of choline in suprarenal extracts thirty five years ago.

Space is not available for a more complete analysis of this book, it represents a class of literature in endocrinology that unfortunately is rapidly increasing in volume.

**La syphilis expérimentale. Étude critique et nouvelles recherches** Par G. Gastinel, professeur agrégé à la Faculté de médecine de Paris, et R. Pulvenis, chef de laboratoire à la Faculté de médecine de Paris. Monographie du laboratoire de bactériologie de la Faculté de médecine de Paris. Papier. Price 45 francs. Pp. 244 with 23 illustrations. Paris: Masson & Cie, 1934.

This monograph deals with a critical study of what has been accomplished in experimental syphilis in the relatively short space of thirty years and with some of the authors' recent investigations, particularly on the Meicke reaction. The major portion of the book is devoted to experimental syphilis of the rabbit and the mouse and to a discussion of various phases of syphilitic immunity. The importance of a biologic point of view in the evaluation of experimental results is properly emphasized, particularly with respect to the application of such results to problems of human syphilis. An essential requirement toward the achievement of the necessary biologic point of view would seem, however, to include a comprehensive and critical first-hand experience with the experimental infection in all its various aspects. For this reason it is to be regretted that the authors did not observe in their experimental material the rich variety and diversity of generalized lesions, which are a characteristic feature of

the infection in the rabbit. Such an experience is an invaluable aid to a better understanding of the many factors that should be taken into account in either a general or a particular consideration of the disease. The comparatively large space allotted to syphilitic infection of the mouse reflects the extent of contemporary interest in the subject. Until further work has demonstrated that the condition has other than what one may term an "animal test tube" significance, it would seem advisable to suspend judgment on its importance with respect to both experimental and human syphilis. The large number of references to the literature is impressive and should be of value to the laboratory worker and to the clinician interested in various phases of experimental syphilis. The authors have achieved an enviable record in their summaries of the essential points of the papers under discussion.

**Histopathology of the Teeth and Their Surrounding Structures.** By Rudolf Kronfeld M.D. Professor of Special Histopathology Director of Department of Research Chicago College of Dental Surgery. Cloth. Price \$7. Pp. 479 with 385 illustrations. Philadelphia: Lea & Febiger 1933.

This is by far the most satisfactory textbook on this subject in English and is comparable only with the books in German by Euler and Meyer and by Sigmund and Weber covering approximately the same ground. The excellent illustrations, for the most part original, are chiefly photomicrographs of sectioned human material and in a great many instances include teeth, soft tissues and bone in the same specimen. The subject matter is well organized, clearly presented and not rigidly limited to the presentation of the histologic picture of oral diseases. For example, in the chapter on dental caries six pages is devoted to a discussion of the clinical characteristics of the disease and experimental research. As stated in the introduction, comparatively little emphasis is placed on processes that have been presented adequately in earlier publications and textbooks and that others relatively new or unknown to the profession are considered more in detail. Except for dentigerous and median maxillary cysts, the subject of tumors and cysts is not included in the book. Each chapter is followed by an extensive bibliography. There is an adequate index. This book is heartily recommended to both dental students and others interested in oral microscopic changes.

**Features in the Architecture of Physiological Function.** By Joseph Barcroft CBE MA FRS. Cloth. Price \$5.50. Pp. 368 with 106 illustrations. New York: The Macmillan Company. Cambridge England: University Press 1934.

This book is a philosophical discussion of the mechanisms of the body whereby the internal conditions of existence are maintained at that nicety of adjustment necessary for man's intellectual supremacy. The experimental evidence for the supporting current biochemical and physiologic concepts are stressed constantly and the bibliography is conveniently given at the end of each chapter. There is a broad consideration of such details of the 'fixité du milieu intérieur' as hydrogen ion concentration, temperature, oxygen supply and blood sugar, with the conclusion that variations in the factors are conditioned largely by the nervous system which in turn proves to be the chief beneficiary of the resulting stable state. There are three chapters on storage materials, including glycogen, lipids, oxygen, iron, copper and blood. The high spot of interest in this fascinating book is the section which supports the view that every adaptation is an integration. As an example the author discusses fetal respiration, pointing out the part played by the maternal organism as well as by the fetus, anoxia, drawing on his own extensive experience as a physiologist, and the adjustment to muscular exercise, correlating in lucid style the considerable pertinent information currently available and indicating other, as yet unknown possibilities. As contributory considerations of the vital equilibria the all or none' relation the principles of antagonism and of maximal activity, as well as the duplication of mechanism, are discussed. In making use of both the classic and the more recent experimental observations, the author combines a discriminating open-mindedness with a benign conservatism. Doubtless there will be readers who object to certain apparent inaccuracies of statement and to the teleological flavor of certain portions, but when the author states that not till the machinery for the

exact regulation of the properties of the blood had been perfected up to a certain point did—I would say could—the magnificent development of man's intellectual powers take place," he effectively discriminates between the purposeful and the logical. Basing his conclusion on the developments in physiologic chemistry, the author chooses to 'regard a phenomenon (structural or functional) as more likely to have a significance than not.' The field has been viewed at once with close attention to detail and with magnificent detachment, the treatment is informal, at times personal, at others even whimsical, but always authoritative.

**Aids to Pathological Technique.** By David H. Haler M.B. B.S. Pathologist. Infants Hospital London S.W. 1. Cloth. Price \$1.50. Pp. 187 with 18 illustrations. Baltimore: William Wood & Company 1933.

This booklet, another of the "Students Aids Series," contains a brief description of the laboratory procedures most frequently employed in bacteriology, hematology, cytology, parasitology and biochemistry. The writer has presented one example of each method, which he has found to work best in actual practice. For medical students reviewing for examinations, and also for those doing laboratory work, this booklet contains concise and accurate instructions for the various examinations. There are also tables for recognition of *Endamoeba histolytica*, malarial parasites, normal hematologic appearances, and blood chemistry. A brief description of the preparation of culture mediums is added.

**La gangosa et les rhino-pharyngites mutilantes des tropiques.** Par le Dr. Georges Gallnier de la Faculté de médecine de Paris. Paper. Pp. 87. Paris: Jouve & Cie 1934.

This brochure discusses in considerable detail the subject of gangosa. As the author states in his historical notes, the name 'gangosa' is Spanish and means "nasal voice." This nomenclature is derived from the fact that the ulceration and destruction, partial or otherwise, of the palate produces the peculiar nasal twang. The first chapter dwells considerably on the geographic distribution of the disease (it is encountered mostly in Oceania) and also discusses the classification of the condition. Attention is called to the fact that in some phases it resembles yaws, syphilis, leprosy and sometimes tuberculosis in its involvement of the nose, mouth and pharynx. It is interesting to know it was members of the United States naval medical forces who were among the first to describe this disease in Guam. Then follow chapters on clinical forms and symptomatology. In speaking of the pathology, attention is called to the fact that the lesion is that of a granuloma. The Bordet-Wassermann reaction is often positive in these cases, just as it is in syphilis and in yaws. The differential diagnosis is often difficult and the author devotes considerable space to this phase of the subject. Several case histories are given at the end of the monograph and a rather complete bibliography is appended.

**The Clinical Management of Horseshoe Kidney. A Study of Horseshoe Kidney Disease Its Etiology Pathology Symptomatology Diagnosis and Treatment.** By Robert Gutierrez A.B. M.D. F.A.C.S. Chief of Clinic of the Department of Urology James Buchanan Brady Foundation of the New York Hospital. With a foreword by Dr. Edmond Papin. Cloth. Price \$3. Pp. 143 with 52 illustrations. New York: Paul B. Hoeber Inc. 1934.

The author has made a thorough study of a subject that is of great interest not alone to urologists but to all clinicians interested in differential abdominal diagnosis. Renal fusion has not been recognized frequently on clinical examination and is usually first discovered on abdominal exploration or postmortem examination. The author believes that the symptoms caused by renal fusion are so distinct that they can be regarded as a separate clinical entity, to which he gives the name of horseshoe kidney syndrome. Although it is true that various symptoms such as the author describes are noted in some cases of renal fusion, it is open to question whether they are definite enough to be regarded as a diagnostic entity. All forms of anomaly in the urinary tract are subject to secondary pathologic complications, which are the usual cause of symptoms rather than the anatomic condition itself. It must also be remembered that various intra abdominal lesions may be present which can cause symptoms such as he describes and, unless clinically recognized, they may be easily overlooked. That

the anomalous position of the horseshoe kidney exerts pressure on the adjacent nerves or blood vessels sufficient to cause pain has been previously inferred by other observers but no definite evidence has been offered to prove this point. It is well known that renal fusion as well as other anomalies of renal position, such as renal dystopia and incomplete rotation, are frequently discovered in the course of routine urography, which cause no clinical symptoms.

The author believes that horseshoe kidney may be the cause of constipation and gastro-intestinal disorders. He does not, however, make it clear why renal fusion should cause such disturbance. In common with other observers, he refers to the so-called Rovsing sign as valuable in the recognition of horseshoe kidney. Other observers, however, have frequently failed to find this sign and have noted that similar reaction may be observed when no anomaly is present.

The author has made a careful study of the urographic data observed with horseshoe kidney and has added some interesting observations to those previously described. Included in the latter is a description of a urographic triangle with a minimum lower angle, which he has repeatedly observed with horseshoe kidney. The volume is profusely and graphically illustrated, and careful perusal of the various roentgenographic data which he has described should lead to more frequent recognition of this anomaly, particularly if excretory urography is employed in a routine way in doubtful abdominal conditions. The chapter on treatment is brief but contains considerable data of value.

**Ultra Violet Therapy In Eye Disease with a Review of the Action of Other Forms of Radiant Energy.** By Frank W. Law, M.A., M.D., B.Chir., Assistant Surgeon, Central London Ophthalmic Hospital. Foreword by Sir Stewart Duke Elder, M.A., D.Sc., M.D. Boards. Price 5/- Pp 78. Published for the Middlesex Hospital Press, London. John Murray 1934.

The author reviews briefly the existing knowledge of light rays and discusses those of beneficial or therapeutic value. He reviews the use of ultraviolet radiation in its action on the eye, gives the technic for its application, and cites a number of case reports with his results in many eye conditions. His statement that ultraviolet therapy is of most value in "symptomatic" diseases of the eye and that in general local radiation it is of more value in its own sphere than in general application summarizes his view of the matter. He concludes "General phototherapy has less value in ophthalmology than previous writings suggest, it is nevertheless a very useful adjunct in treatment, especially in such cases as phlyctenular disease, blepharitis and some forms of iridocyclitis. Local phototherapy is of the utmost value in the treatment of all kinds of superficial lesions of the eye, in deeper lesions action is less certain." He devotes little space to radium therapy and combines the work on radium and x-rays because of their similar action. About radium he concludes "The claims made for the therapeutic value of radium in ophthalmic conditions, especially in America, are too diverse and too enthusiastic. Radium is of proved value in the treatment of epibulbar and orbital neoplasms, especially of the malignant or vascular benign variety. The encouraging results obtained by its action on intraocular malignant growths justify its further use in this field." Infra-red rays play no part as a therapeutic agent in ophthalmology and are given little space. The book is brief and contains the essentials of technic for the use of these therapeutic agents but adds little to the existing knowledge of the agent. It is chiefly a summary of the author's results at the Middlesex Hospital.

**Recent Advances in Medicine. Clinical Laboratory Therapeutic.** By G. E. Beaumont, M.A., D.M., F.R.C.P., Physician with charge of Outpatients, Middlesex Hospital, and E. C. Dodds, D.Sc., Ph.D., M.D., Courtauld Professor of Biochemistry in the University of London. Seventh edition. Cloth. Price \$4.1p. 485 with 58 illustrations. Philadelphia: P. Blakiston's Son & Company, Inc. 1934.

This edition is evidence of deserved popularity. There are many additions to the text and illustrations. The chapter on hormones and vitamins is entirely new and gives a timely review of present knowledge. The sections on the blood and the heart and kidney are thoroughly revised and include all recent contributions. The text is concise and should be useful not only to the student but also to the general practitioner.

**Traité de médecine des enfants.** Publié sous la direction de P. Nobécourt et L. Babonneix. Secrétaires de la rédaction: J. Cathala et J. Hutinel. Tome I [Maladies de la nutrition de la croissance et la pathologie des glandes endocrines]. Boards. Price 170 francs, 700 francs per set of 5 volumes. Pp 989 with illustrations. Tome II [Les infections Maladies du sang Affections des organes hémato-poïétiques]. Boards. Price 170 francs. Pp 960 with illustrations. Tome III [Les affections de l'appareil circulatoire celles de l'appareil respiratoire, le début des affections de l'appareil digestif]. Boards. Price 170 francs. Pp 1086 with illustrations. Tome IV [Les affections des voies digestives (fin), celles de l'appareil génito-urinaire les intoxications les affections des os la dermatologie l'ophtalmologie la psychiatrie]. Boards. Price 170 francs. Pp 956 with illustrations. Tome V [La neurologie la thérapeutique et la table alphabétique générale des matières des cinq volumes]. Boards. Pp 876 with illustrations. Paris: Masson & Co. 1934.

This system of pediatrics, appearing in French in five beautifully bound volumes, represents the writings of the best minds in French pediatrics today. These volumes supersede the three older French treatises on pediatrics and contain freshly written and modern material. The editors-in-chief, Pierre Nobécourt, professor at the University of Paris and director of the Hospital des enfants malades, and Leon Babonneix, are men of international reputations. They were aided by Jean Cathala and Jean Hutinel, who unfortunately died shortly before the volumes were completed.

The material in the five volumes is divided as follows. Volume I contains the general table of contents and introduction, and the chapter on normal growth and development, diseases of nutrition and pathologic endocrine disturbances. Volume II deals with the acute infectious diseases and diseases of the blood and blood-forming organs. Volume III contains the chapters on the circulation, respiration and digestive tract. Volume IV deals with disorders of the genito-urinary tract, the mouth, the skin and the eyes. Psychiatric disturbances and accidental poisoning are included in this volume. Volume V, the concluding volume, deals with neurology and materia medica, and therapeutics, and contains the general alphabetical index to the five volumes of the system.

As in all systems to which numerous authors have contributed, the style, handling of material and value of the various chapters vary. Among those which stand out for their excellence in volume I are the chapters on growth and development by Nobécourt and his assistants, and the chapter on prematurity by Paul Rohmer of Strasbourg. In volume II there is an excellent chapter on diphtheria by Grenet, with references. The chapter on typhoid could have dealt more specifically with the peculiarities of this disease in infants and young children. The chapter on scarlet fever, by Gautier, is excellent in character. His analysis of the etiology and serum therapy of this disease is well balanced. The chapter on congenital syphilis by Pehu is monographic. It consists of more than 150 pages of excellent material and is written by an authority on this subject. A complete list of references is given at the end of each topic discussed. The chapters on blood are unfortunately weak. The colored plates are far below standard. Descriptions of fourth, fifth and sixth diseases may be found in volume II and are described in four pages for the elucidation of the uninitiated.

Volume III contains the chapters on the heart and circulation and on respiratory and gastro-intestinal disorders. The treatment of the cardiovascular system is hardly adequate, while the diseases of the upper respiratory tract and the pneumonias are better handled. The chapter on bronchiectasis is full and excellent and the subject of pulmonary tuberculosis is well handled. R. A. Marguezy has done well with diseases of the mediastinum, tracheobronchial adenopathy being remarkably well illustrated and discussed as are the tumors of the mediastinum. In the chapter on foreign bodies in the esophagus it seems odd to see an illustration of the technic for removing a plate or bridge of false teeth in a treatise on pediatrics. Lereboullet has written an excellent article on vomiting in infants and children, including an excellent description of hypertrophic pyloric stenosis. The chapters on the nutritional diseases, dyspepsias and alimentary intoxication by Cathala are interesting in that they give the French point of view. Rohmer has done well with the chapters on megacolon and celiac disease.

In volume IV the best chapters are again those by Pehu on the bone changes in congenital syphilis. The chapter on diseases of the skin is well illustrated, while the chapter on

# Medicolegal

**Contract to Testify as Expert Witness Valid** — The plaintiff, a physician, had professionally observed the condition of the defendant's wife, but whether with a view to treatment or with a view to giving evidence the reported decision does not make clear. Subsequently the defendant desired the plaintiff's evidence in a suit to which the defendant and his wife were parties, as to blows or bruises on the wife's body or anything in her condition that might lead the plaintiff to believe that she had been subjected to violence or physical mistreatment. The plaintiff expressed his unwillingness to testify, and a subpoena was served on him. After the service of the subpoena the defendant promised the physician to pay him for testifying the amount that he would receive for a gallbladder or appendicitis operation. The plaintiff then attended the trial, gave expert testimony and sent the defendant his bill. When the defendant refused to pay, the plaintiff brought action against him. Judgment was given for the plaintiff and affirmed by the supreme court. The defendant appealed to the Court of Errors and Appeals of New Jersey.

It is quite obvious, said the Court of Errors and Appeals, that the plaintiff testified as an expert. He not only stated the facts observed by him but also expressed his professional judgment as to the condition he found and its cause. The question was squarely presented, therefore, whether a contract such as the plaintiff made was void as against public policy. It is quite clear, said the court, that all knowledge which a witness has of the actual facts of litigation, whether the witness be a professional man or a layman, is available and that a witness is amenable to subpoena and compellable to give evidence of such facts. But the experience, training and skill of a professional man, acquired by years of study and practice in a given profession or calling, are not the property of the litigants. They belong to the professional man in his chosen occupation. Neither justice nor public policy, in the opinion of the court, forbids that the expert shall retain such knowledge and skill free from disclosure otherwise than by his voluntary act. This is true whether disclosure be sought for compensation for the exercise of his skill, or in the expression of his professional judgment privately, or as a witness in a court of justice. The right to compensation for services so rendered, the court thought, was generally recognized by the bar of New Jersey and compensation paid accordingly. The testimony of experts often involves long and tedious preparation for testifying, as well as the giving of results of training and experience to the appointed judicial investigators. It would be unjust and without legal justification to withhold payment therefore.

"Our conclusion," said the Court of Errors and Appeals, "is that an expert witness cannot as such be compelled to give testimony in response to subpoena, and, if such expert testimony is called for and given, it is the right of such person to contract for and receive proper and adequate compensation therefor."—*Stanton v Rushmore* (N J), 169 A 721

**Evidence Presumption that Woman is Capable of Childbearing Not Absolute** — The testator, after making certain bequests, devised the residue of his estate to a trust company, in trust to pay an income to his daughter during her life and on her death to her lawful issue. If she died without issue, the residuary estate was to be distributed among certain charitable institutions and societies. At the time of the testator's death, the daughter was 50 years old. Seven years before that time she had had her uterus fallopian tubes and both ovaries removed. Unless under such conditions she was capable of bearing children, the residuary estate would inevitably pass on her death to the charitable institutions named in the will, and the residuary estate, less the value of the daughter's life interest in it, was a charitable bequest, to be deducted from the gross estate before computation of the estate tax.

The commissioner of internal revenue contended that the age of the daughter and the sterilizing operation to which she had been subjected were immaterial, that the law conclusively presumed that she was capable of bearing children as long as she lived, and that the legal presumption controlled even though

the organs of reproduction had been completely removed. He fixed the value of the gross estate accordingly and demanded payment of the federal estate tax on that basis. The administrator of the testator's estate paid the tax and then filed a claim for a refund. He contended that the commissioner of internal revenue erred, that in computing the value of the estate the commissioner should have deducted the value of the residuary estate, less the daughter's life interest in it, since it was certain to go to charitable institutions and societies on her death, as she was incapable of bearing offspring. He brought suit against the United States in the United States court of claims to recover the amount of the excess tax paid. The court entered judgment in the administrator's favor,<sup>1</sup> and the United States, by writ of certiorari, carried the case to the United States Supreme Court.

Where only the element of age is involved, said the Supreme Court, the presumption that a woman is capable of childbearing has been held to be conclusive, but the conclusiveness of the presumption even in such cases has not been universally upheld. The English courts have given the presumption a considerable degree of flexibility and in a large number of cases have refused to give it a conclusive effect. American courts have adhered to a more rigid view. Few cases have arisen in which elements other than age were present, and the conclusive character of the presumption in such cases is by no means established. The presumption of a woman's continuing capacity for childbearing originated when medical knowledge was meager, centuries before the discovery of anesthetics and before surgical operations were undertaken such as that to which the testator's daughter was subjected. Not until a comparatively recent period was the effect of such an operation determinable and the fact incontrovertibly established that a woman so operated on is permanently incapable of bearing children. The Supreme Court could see no ground of expediency or policy that called for a hard and fast application of this presumption of incapacity to bear children, when facts put beyond the range of doubt the absence of such capacity. The birth of a child to the daughter of the testator after his death was so plainly impossible that as a practical matter hazard disappears from the problem, if her interest had been offered for sale in the open market during her lifetime, a suggestion of the possibility of issue would have been ignored by every intelligent bidder as utterly destitute of reason. The judgment of the court of claims in favor of the administrator was affirmed.—*United States v Provident Trust Co*, 54 Sup Ct 389.

**Workmen's Compensation Acts Paralysis Agitans Following Trauma**—On Nov 19, 1928, the hair of the decedent, an able bodied woman about 45 years old, caught on a revolving shaft in the cannery in which she was employed. A strip of her hair was pulled out, about an 1½ to 2 inches wide and extending from the base of the skull almost to the forehead. She continued to work for a short period after the accident and then was taken home, where she remained for eight days. When she returned to work she was so nervous that she wept at the sight of the cannery and had to be assigned to other duties in a part of the building other than that in which the accident had occurred. She worked until December 7, when the cannery closed. She did not go back to work but did perform her household duties. Gradually she lost strength and her general health failed. About two years after the injury, numbness was discovered in her right hand and she was unable to hold a sewing needle. Late in 1931 tremors of the hand and arm became apparent. These conditions extended to other parts of the body, with a certain degree of rigidity of the members affected, so that she became totally disabled and died.

During her lifetime she filed a claim for compensation with the industrial accident board, which the board denied. An appeal was taken to the district court, Kootenai county. The claimant having died, her son was appointed administrator of her estate and substituted as a party plaintiff. From an order of the district court affirming the order of the industrial accident board denying compensation, the administrator appealed to the Supreme Court of Idaho.

Four physicians testified before the industrial accident board on behalf of the claimant and one on behalf of the canning

company. All five agreed that the claimant was suffering from paralysis agitans and that the exact cause of the disease is unknown. Shock, fright, trauma, injuries, infections and syphilis, it was testified, precipitate or aggravate the disease or are its exciting causes. The four physicians who testified for the claimant testified that the injury received was the exciting cause of the claimant's paralysis agitans. The physician who testified on behalf of her employer, the canning company, was positive that her injury in no way contributed to or caused her illness. If the injury had been the exciting cause, he testified, the tremors, paralysis and rigidity would have appeared shortly after the injury, at least within a few weeks and under no conditions beyond one year. The deceased, this witness contended, did not receive a severe brain injury, she was not thrown against the revolving shaft, nor did she fall. Hair grew where hair had been pulled out, showing that there was no severe scalp injury. The deceased, in his opinion, suffered from encephalitis and phlebitis, and encephalitis is one of the principal causes of paralysis agitans. The encephalitis and phlebitis, he believed, were probably the exciting causes of the claimant's paralysis agitans.

There is in this case, said the Supreme Court, a substantial and direct conflict in the evidence as to what was the exciting cause of the paralysis with which the deceased was afflicted. All the medical testimony for the claimant was to the effect that the exciting cause was the injury she had sustained, the medical testimony on behalf of the canning company was to the contrary. There was ample evidence to support the findings, conclusion and award made by the industrial accident board and affirmed by the district court, to the effect that the injury was not the exciting cause of the paralysis agitans with which the deceased was afflicted. The Supreme Court, therefore, affirmed the judgment of the district court denying compensation.—*Lorson v Callohan Canning Co of Coeur d'Alene (Ida)*, 27 P (2d) 967.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Carcinoma of the Rectum in Youth**—Ross shows that carcinoma of the rectum is not limited to the declining decades of life by presenting three cases in patients 21 years of age and younger. The relative rarity of cancer prior to the so-called cancer age appears still to be a definite factor in preventing the early correct diagnosis of such lesions. This reluctance to make a diagnosis of cancer because of the youth of the patient was responsible in the first of the three cases for the rectal symptoms being attributed to tuberculous stenosis and in the third case it led to an initial diagnosis of ulcerative colitis. A review of the literature furnishes adequate evidence that cancer, while uncommon, is by no means a rare disease of youth. Persons less than 30 years of age appear to comprise from 1 to 3 per cent of those afflicted with carcinoma. Rectal cancer accounts for a proportion of these youthful victims of cancer. From 2 to 4 per cent of all rectal carcinomas occur in persons less than 30 years of age. The occurrence of rectal carcinoma in patients less than 20 years of age is sufficiently uncommon to warrant more than passing notice. One of the author's cases is the sixtieth thus far reported. Rankin and Comfort found little variation in the symptomatology of rectal cancer with the age of the patient. The principal symptoms in all cases were a change of intestinal habit (constipation or diarrhea) and rectal bleeding. It was found, however, that carcinomas arising in the early decades of life are apparently more malignant as indicated by the shorter duration of symptoms, the greater number of inoperable cases, and the decreased percentage of cures lasting three and five years. Each of the growths was readily palpable on simple digital rectal examination. No special laboratory procedure was needed to establish a firm clinical suspicion of the nature of the malady.

**Primary Carcinoma of Liver**—Culpepper and von Haam report a case of primary carcinoma of the liver in which no symptoms were observed referable to the liver which was the site of the primary lesion. Histologically the liver showed the beginning of a cirrhotic process with a slight increase of the periportal fibrous tissue and some signs of liver cell regeneration. The two complications that led to the death of the patient and dominated so exclusively the clinical picture were

tumor thrombosis of the inferior vena cava and metastasis of the tumor to the right auricle of the heart. Invasion into the blood vessels is one of the characteristic features of primary cancer of the liver. Statistics show that the portal branches of the liver vessels are far more frequently and earlier invaded than the hepatic veins or the branches of the liver artery. This peculiar fact explains the rapid spread of the tumor in the liver itself and the later and rare appearance of extra-hepatic metastasis. If the tumor has penetrated into the large branches of the hepatic veins, it may or may not spread into the inferior vena cava and lead to complete or partial obstruction of this vessel. Complete obliteration of the inferior vena cava by a tumor thrombus is rare. The tumor thrombus extended about 1 cm into the vena cava in the direction of the blood stream. The thrombus below the opening of the hepatic veins into the vena cava was only a secondary blood thrombus. The tumor node in the right auricle of the heart was completely separated from the thrombotic process in the vena cava and represented a metastasis of the tumor to the heart. The tumor mass in the right auricle was larger and firmer than the tumor thrombus in the inferior vena cava. It was attached to the endocardium of the auricle and reached like a ball valve into the atrium of the heart. Macroscopically, the tumor in the right auricle had the appearance of being an older growth than the friable and more loose tumor thrombus in the vena cava, an opinion that is supported by clinical data. The complaints of the patient were mainly shortness of breath and swelling of the ankles, which was symmetrical and responded favorably to therapy for some time. The kidney function could also be greatly increased in the beginning but not in the later stages of the disease. The classic diagnostic criterion for thrombi of the inferior vena cava, namely, collateral circulation, was not observed. The patient came to the hospital with beginning heart failure caused by the tumor in the right auricle, later, the tumor thrombus of the inferior vena cava developed and hastened death. A ball valve action of the huge tumor mass in the right auricle might have caused the sudden death of the patient. The tumor metastasis to the heart was apparently the cause of the cardiovascular symptoms, which were the only complaints of the patient. For this reason, the case represents a pathologic and clinical rarity.

**Complement Fixation Test for Amebiasis**—Weiss and Arnold employed this test in eight cases of acute and nineteen cases of chronic amebiasis, as well as in sixty-one carriers. Blood samples were obtained and the results were later compared with the feces observations and the type and duration of treatment. The results of treatment show that the stool becomes negative before the complement fixing antibodies disappear from the serums. The discrepancies between the feces examinations for parasites and the serologic blood tests are found in the weakly positive group of patients who have been treated and whose feces are becoming negative.

**New Dye for Diagnostic Gastro-Intestinal Studies**—Taylor administered orally or by enema brilliant blue FCF to twenty or more patients presenting a variety of disease conditions. In no case was there any gastro-intestinal or general toxic reaction, although the dose of dye ranged from 300 to 500 mg. If much larger doses were given, a slight diarrhea resulted. When the dye appeared in the formed stool, the line of demarcation was sharp and the disappearance from the stool also was definite though not quite so sharp. With this range of dosage there was no pigmentation of the urine by the dye, thus indicating absence of systemic absorption. The rate of travel through the intestinal tract varied with the patient or the disease, with a normal appearance in the stool in about twenty-four to thirty-six hours and a disappearance in about forty-eight to seventy-two hours. Fecal fistulas from various sites along the gastro-intestinal tract showed the passage of the dye. At the cecum, the dye appeared in from two to five hours, while in the descending colon it appeared in from six to nine hours.

**Parasacral Anesthesia in Obstetrics**—Tucker and Benaron present the following results obtained with parasacral anesthesia in fifty operative obstetric cases. 1 Parasacral anesthesia is practical for major operative obstetric cases. Relaxation of the uterus occurs for from fifteen to twenty minutes following the injection and in some cases is sufficient for version and extraction, for manual rotation of a posterior head and for the Pinard maneuver in bringing down a foot in single breech. It is of value in breech deliveries, giving marked relaxation of the entire pelvic floor, thus facilitating all the maneuvers for the extraction of the aftercoming arms and head. Episiotomy and perineorrhaphy, Dührssen's incisions and trachelorrhaphy may be painlessly done. Traction pain is abolished, and a difficult application of forceps can be

painlessly performed, with the added advantage of utilizing the mother's auxiliary powers. 2 The engaged head offers no obstacle to the induction of this type of anesthesia. 3 There is no appreciable alteration of blood pressure or pulse rate, and the procedure is unattended by any signs of shock or collapse. 4 The loss of blood in six cases was above normal. 5 The puerperium was in no way affected by the procedure. 6 In two cases there was complete failure of anesthesia, and ether was resorted to. 7 In seven cases it was necessary to complement parasacral anesthesia with local infiltration in order to perform episiotomy and repair painlessly. The authors point out that in a teaching clinic, in which the duration of an operation is prolonged of necessity, this type of anesthesia is more satisfactory than inhalation methods. It is a valuable adjunct to the armamentarium of the obstetrician, especially when an inhalation anesthetic is contraindicated. This type of local anesthesia produces a minimum of shock to the patient and its particular sphere lies in the class of cases requiring a difficult, time consuming operative procedure.

**Evaluation of Maternal Nitrogen and Mineral Needs**—Macy and Hunscher state that evidence from an analysis of various types of quantitative chemical and physiologic data on the nutritive demands of fetal and maternal metabolism indicates that a specific scientific dietary dictum may be advantageous during reproduction in endowing the child with nutritional stability, protecting the maternal tissues from metabolic loss, and providing for a storage to meet all needs of maternity. From an evaluation of maternal nitrogen and mineral needs during embryonic and infant development, it seems advantageous to provide a daily supply of from 70 to 100 Gm of protein, and a minimum of 1.6 Gm of calcium, 2 Gm of phosphorus, 0.3 Gm of magnesium and 20 mg of iron. From available scientific evidence, human lactation requires a greater amount of all food nutrients than does pregnancy. The necessity of fortifying the maternal diet with sufficient amounts of vitamins is indicated.

**Copper Ionization for Treatment of Leukorrhea**—Tovey outlines a method of copper ionization for the treatment of leukorrhea in virgins in which a special speculum is used which consists of a cystoscopic tube with a handle large enough for the patient to hold. A small copper intracervical electrode is inserted up to the internal os. A large indifferent electrode is placed under the back, and from 4 to 10 milliamperes of current is given with the positive pole. After twenty minutes the current is turned off and the negative current is used to release the copper electrode. In case of a pinhole os the tip of the copper electrode is pressed against the external os and the negative current is turned on until the os dilates, after which the current is reversed and copper ionization is given for twenty minutes. In one case of pinhole os with an enlarged dilated cervix, half a drachm of foul, colon-smelling secretion was freed when the os was dilated. The author has treated twenty-five virgins, from 15 to 25 years of age. He considers copper ionization an extremely satisfactory method of treatment. From four to eight treatments are necessary to cure the cervicitis. Treatment is painless.

**Immunization with Alum Precipitated Tetanus Toxoid**

—The toxoid that Bergey and Etris employed was prepared from a toxin containing 10,000 minimal lethal doses per cubic centimeter. The toxin was detoxified with 0.4 per cent formaldehyde. The toxoid was precipitated with 2 per cent of potash alum, washed twice with and resuspended in physiologic solution of sodium chloride. Merthiolate was added to make a 1:10,000 dilution. The addition of potash alum to toxoid is believed to retard the rate of absorption and thereby appears to increase the antigenic action, so that it might be used in doses of 1 cc. The study of the antigenic effect of a single dose of alum precipitated tetanus toxoid was started on thirty-three adults and on a boy 10 years of age. None of the specimens of normal blood showed the presence of measurable amounts of antitoxin. Immediately after withdrawal of the blood each person received an injection of 1 cc of the alum precipitated tetanus toxoid by deep subcutaneous injection. The serums of eight of the thirty-four persons that had received the alum precipitated tetanus toxoid from twenty-five to forty-two days earlier were tested for antitoxic content, and four, who were within the age group of from 20 to 30 years showed from  $\frac{1}{4}$  000 to  $\frac{1}{2}$  000 unit of antitoxin per cubic centimeter. The other four showed only traces of antitoxin. The four that showed measurable amounts of antitoxin had received the dose of antitoxin only twenty-five days prior to the tests. The serums of two individuals, who were more than 50 years of age, when tested sixty-eight days after treatment with tetanus toxoid showed only a trace of antitoxin. The authors state that since guinea-pigs receiving a dose of 1 cc of the alum precipitated tetanus toxoid developed as much as one half unit of antitoxin in 1 cc of serum in eight weeks, it is believed that human beings after an injection of a dose of 1 cc will show at least  $\frac{1}{2}$  000 unit of antitoxin in from six to eight months. The development of tetanus antitoxin in the blood of persons is slow and requires several months before appreciable amounts of antitoxin can be detected. Tetanus toxoid should not be used for therapeutic purposes. It should not be injected into a nonimmune person at the time of receiving an injury. Persons actively immunized with tetanus toxoid when injured should receive another dose of tetanus toxoid while persons who are not actively immunized should receive a dose of tetanus antitoxin. In such an individual active immunization may be carried out by giving a dose of tetanus toxoid about two weeks after the receipt of a dose of tetanus antitoxin following an injury. The points of special importance in the use of alum precipitated tetanus toxoid are the induction of an active immunity in from three to six months, the absence of either local or general reaction from

the dose of alum toxoid except slight local reaction in occasional persons who are highly sensitive to the proteins contained in culture mediums, and the absence of danger of sensitizing the individual to horse serum proteins such as may occur from repeated prophylactic doses of tetanus antitoxin when used for prophylaxis following injuries.

**Scarlet Fever Toxin Successful Immunizing Agent —**

After giving 49,165 doses of scarlet fever toxin, 20,278 primary Dick tests and 12,713 Dick retests in the Gary schools, Nesbit and Thompson found that scarlet fever immunization as recommended for use by the scarlet fever committee is a safe procedure and that it is a valuable asset to a community as a prophylactic measure. During the eight years preceding 1925, when the school census varied from 9,811 to 18,438, there were twenty six deaths from scarlet fever among 1,241 cases reported. In the following eight years, up to the present time, since immunization has been carried on, the school census has varied from 20,472 to 28,032, and there have been 1,147 cases with thirteen deaths. In giving Dick tests it is important that exactly 0.1 cc of test material is injected intradermally, that the potency of the material is checked and that the tests are read from twenty-two to twenty-four hours later in clear daylight. If there is a question as to whether the test is negative or positive, it should be considered positive. Some severe but no serious reactions have resulted from the 49,165 doses of scarlet fever toxin. Of 114 who began doses, 107 finished, indicating the infrequency of severe reactions to doses. During the past year 2,055 primary Dick tests were given of which 762, or 35 per cent, were negative. Of 368 who were given the usual five doses and given a Dick retest two weeks later, 788 or 91 per cent, were negative. During the past year 171 persons were retested who had had the usual five doses five or more years previously and 139, or 81 per cent, remained negative. Of the 18,980, the total number of primary Dick tests read during nine years, 46 per cent have been negative. Among a group estimated at 10,000 who have completed scarlet fever toxin doses, there have been only nine persons who had a negative retest who have later been reported with scarlet fever.

**Atelectasis in Pulmonary Tuberculosis —**

Stivelman states that acute massive atelectasis is rarely observed in pulmonary tuberculosis but that it may occur when a large bronchus is plugged as a result of hemoptysis. Chronic massive atelectasis in phthisis is frequently confused with extensive unilateral pleuropulmonary fibrosis. Cases may run a benign course, but, when dyspnea develops as a result of extensive mediastinal deflection may be effectively treated with artificial pneumothorax. Confluent lobular atelectasis occurs frequently and early in the course of phthisis. It encourages local fibrosis by producing a local tissue respiratory deficiency. Tubercle bacilli, being strict aerobes are markedly attenuated when they are deprived of an adequate amount of oxygen. Lobular atelectasis by impairing the local circulation materially diminishes the available oxygen supply in the area involved, and so adversely affects the growth of the tubercle bacilli. All forms of atelectasis are to be seen in lungs treated with artificial pneumothorax. This accounts for the rapid fibrosis of lesions

under collapse therapy. The collapse of cavities in negative-pressure pneumothoraces is brought about by the absorption of the air they contain following the kinking of their draining bronchi. The high negative pressure thus created within them forces an approximation of their walls. When this is accomplished, healing of the cavity may continue uninterruptedly if further collapse is judiciously maintained.

**Experimental Tuberculous Bacilluria**—Montgomery and Allen performed a series of experiments for the purpose of demonstrating whether it was possible to bring about passage of acid-fast bacteria through the normal kidney. Guinea-pigs were given intravenous injections of a heavy suspension of *Mycobacterium avium*, and rabbits were similarly given injections of a heavy suspension of *Mycobacterium phlei*. The urine of these animals was collected by catheterization and examined microscopically, and cultures were taken by appropriate means for the demonstration of acid-fast bacteria. Cultures of organisms similar to those injected were obtained from the urine of guinea-pigs and one rabbit. Two similar experiments were performed, except that the number of bacteria was doubled in an attempt to obtain more striking results. The results were negative in the case of the rabbits, but 82 per cent of the cultures made from the urine of the guinea-pigs were productive of bacterial growth. A fifth experiment was carried out on guinea-pigs in which the urine was collected by aspiration of the bladder at necropsy. A further change was made by introducing a group of guinea-pigs in which *Mycobacterium phlei* was used in place of *Mycobacterium avium*. Positive cultures were not obtained in this experiment. Consequently the positive results of the first experiments were due to contamination of the urine by blood elements that had been liberated through abrasions caused by the introduction of the catheter. The authors conclude that the normal kidney of the rabbit and the guinea-pig is not permeable to the acid-fast organisms used in this investigation, even in the presence of marked and continued bacilluria.

**Chronic Arthritis**—According to Cox and Hill, Cecil's hemolytic streptococcus AB 13 shows a greater serologic selectivity for atrophic arthritis than for any other disease group studied, as evidenced by the percentage of positive reactions in high agglutinin titer. The proportion of serums of patients having atrophic arthritis which contain agglutinins in high titer for AB 13 cannot be accounted for on the basis of (1) previous artificial immunization or (2) previous or concomitant streptococcal infections. No other organism employed in this work was as selective as AB 13 for serums from patients with atrophic arthritis either in the height of the serum titer or in the frequency of positive agglutinin reactions. No correlation was found between agglutinin titers and cutaneous reactions to vaccine of homologous organisms in the patients with atrophic arthritis. Often within a short time a striking unexplained variation of agglutinin titers, not accounted for by clinical developments, occurs in patients untreated by vaccine. In this study there was no regularity in the changes in the

agglutinin titer as a result of vaccine therapy. There is no apparent relationship between the variation in agglutinin titer and the clinical course. A few patients seemed to be benefited by desensitization with vaccine. The improvement in other patients who received vaccine therapy may have been due to other factors impossible to control. The AB 13 agglutinin titer has a definite but limited use as a diagnostic aid in arthritis.

**Necropsy Observations in Osteomalacia**—Gunn and Nadler present the observations of necropsy in a typical case of osteomalacia in a man. Besides the typical skeletal deformities, the pathologic changes of special interest were hypertrophy and hyperplasia of the parathyroids, slight hypertrophy of the anterior lobe of the hypophysis and numerous small calcareous deposits in the kidneys. Only two parathyroids could be found. These were equally enlarged and presented microscopic evidence of mild hyperplasia interpreted as a compensatory condition caused by increased physiologic activity.

**Borderline Ray Therapy in Dermatology**—Dorne and Zeisler found borderline rays superior to x-rays in certain superficial mycotic infections, in localized and disseminated neurodermatitis and in lichenified eczemas. They are also of value in superficial basal cell epitheliomas, especially of the eyelid, in nevus flammeus, in some keratoses and occasionally in senile warts. In a miscellaneous variety of other inflammatory dermatoses the effect of borderline rays is probably equal to that of roentgen rays. In many of the commoner dermatoses occurring about the face, such as acne vulgaris, rosacea, seborrhea and sycosis, the therapeutic effect of the borderline ray is unsatisfactory and it is not considered the method of choice. Conservatism in dosage is recommended. On the basis of their observations the authors do not feel justified in concluding that borderline rays will supplant x-rays in dermatology.

**Method for Obtaining Mixed Venous Blood by Arterial Puncture**—Friedman and his associates describe a modification of the method of Burwell and Robinson for determining the gas contents of "mixed" venous blood. The procedure depends on obtaining blood from a peripheral artery while the subject breathes a gas mixture which has been equilibrated with his venous blood by previous repeated rebreathings. The several procedures involved in the method have been checked by various experiments. Application of the method to dogs has demonstrated that the values found for the blood gases by this indirect method are in close agreement with the gas contents of blood obtained by puncture of the right ventricle. The presence in the lungs of sufficient fluid to produce well marked arterial anoxemia does not invalidate the results. The method involves considerable discomfort to the subject. Its agreement with the modified acetylene procedure constitutes additional evidence as to the validity of the latter in subjects with cardiac disease.

**Blood Cholesterol and Increased Metabolism from Dinitrophenol and Thyroid**—Cutting and his co-workers establish a significant correlation between the basal metabolic rate and the blood cholesterol concentration for human subjects. This correlation was not present when the metabolism was raised by dinitrophenol. Therefore the changes in blood cholesterol present in thyroid disease are not related directly to the metabolic rate but to other actions of thyroid secretion. The stimulation of metabolism by dinitrophenol was as great in patients with initial metabolic rates below 15 per cent as it was in those with higher rates which indicates that the drug may increase depressed as well as normal metabolism.

**Heterophile Antibody Test in Leukemia**—Bernstein found that heterophile agglutinins in the blood serums of twenty one patients having leukemia were confined to low titers less than 1 to 4 in twenty instances. In most of the conditions simulating leukemia, heterophile agglutinins were found over a wider distribution of titers up to 1 to 16. The author presents two clinical histories as examples of instances in which this differential point was of assistance in arriving at a diagnosis. Intravenous administration of horse serum which in a normal person elicits an increase in the concentration of heterophile antibodies, failed in one case of lymphoid leukemia to raise the heterophile antibody titer. In a second case of probable leukosarcoma, horse serum brought about a minimal increase of sheep cell agglutinins. Neither of these patients developed

serum disease. The restriction of heterophile antibody concentrations in leukemia to low titers is in accord with previously known immunologic characteristics of persons having the disease.

**Vaccination Against Acute Anterior Poliomyelitis**—Kolmer and Rule found that a chloroform treated vaccine of monkey poliomyelitic spinal cord in a total dosage of 1 cc by subcutaneous and intracutaneous injection failed to immunize two monkeys against intracerebral inoculations of virus. A sodium ricinoleated vaccine appeared to produce slight immunity in one monkey by subcutaneous injection while intracutaneous injections immunized two additional animals in a more convincing manner. An untreated vaccine by intracutaneous injection immunized one animal successfully but failed to protect two animals when administered by stomach tube. A heated vaccine failed to immunize five monkeys when administered subcutaneously, intracutaneously and by stomach tube.

**Cardiac Irregularities Produced by Ephedrine**—Meek and SeEVERS recorded the effect of ephedrine on cardiac rhythm by the electrocardiograph after intravenous injection of the drug into intact dogs. Doses of from 0.5 to 8 mg per kilogram of weight produce almost at once a stage of marked bradycardia. This more or less quickly merges into a second stage characterized by ectopic extrasystoles and slow ectopic rhythms. These two stages are believed to be largely the result of reflex vagal stimulation from the high blood pressure. The first is a direct inhibition of the normal pacemaker. The second consists of escape phenomena from the lower automatic centers. Coincident with the escape phenomena there is developing a third stage of excitation. This is shown by the slow rhythms occasionally passing into tachycardias. If ephedrine is given after atropine the reflex effects are eliminated and the stage of stimulation is reached almost at once, tachycardias being observed in almost every experiment. Ephedrine also affects cardiac conduction. In the second stage there are various types of block due to reflex vagal stimulation. In the third stage of excitation bundle-branch block and disturbed ventricular

conduction are probably caused by the opening up of abnormal pathways. Doses of from 6 to 20 mg of ephedrine per kilogram of weight begin to show a fourth stage of depression. As the amount injected is raised above 20 mg, paralysis of the upper automatic centers begins to occur and the ventricle may pass into fibrillation. After from 125 to 200 mg of sodium barbital per kilogram of weight there is a high degree of protection against the cardiac effects of ephedrine. Since barbital somewhat increases the normal heart rate but slows it after atropine, it is believed the protection is brought about by a certain degree of vagal paralysis and a simultaneous depression of the automatic centers.

**Action of Estrin in Terminating Pregnancy**—The histologic study of D'Amour and Gustavson of the action of estrin administration during the course of pregnancy indicates that 1 In preimplantation stages, the uterus, when exposed to an adequate dose of estrin, has a hyperplastic mucous membrane, considerably fibrosed, and the secretion in its lumen has practically no coagulable material in it, resembling rather the secretion that dilates the uterus at estrus. 2 Pregnancy in postimplantation stages is terminated by killing the embryo, without necessarily involving any morphologic changes except the absence of the characteristic edema of pregnancy.

**Roentgenologic Diagnosis of Perinephric Abscess**—Shane and Harris conclude that the roentgenographic signs of perinephric abscess must be considered as a valuable adjunct in the diagnosis. The shadow of the psoas muscle was obliterated to some extent in all cases. Some abnormality of the renal shadow was found in thirty-three cases, scoliosis was observed in eighteen cases and elevation of the diaphragm was found in eight of the thirty-two cases in which roentgenologic examination of the thorax was performed. In twenty-two cases an associated pathologic condition was found at operation, stones being present in seventeen. The frequency with which obliteration of the shadow of the psoas muscle occurs on one or both sides, and the frequency with which some degree of scoliosis is found in the course of routine roentgenography, diminish to some extent the clinical value of these data. For instance, the shadow of the psoas muscle was obliterated on one side in 10 per cent of cases and on both sides in 3 per cent. Definite scoliosis was present in 3 per cent, but there were several other films in which it occurred. The roentgenograms were studied in a series of fifty cases of renal calculi, and obliteration of the psoas muscle, or scoliosis was found to some extent in more than 30 per cent of these cases. The roentgenologic signs of perinephric abscess, especially obliteration of the shadow of the psoas muscle or scoliosis, do not necessarily indicate the existence of perinephric abscess and therefore cannot be regarded as pathognomonic. They have a relative importance, however, when considered in conjunction with the clinical manifestations of the disease, that is increased when coincident scoliosis and obliteration of the psoas muscle are observed.

 Septic Abortion, Complicated by Bilateral Lobar Pneumonia Retroperitoneal Abscess and Femoral Thrombophlebitis Report of Case with Recovery H Hertzberg, Washington—p 198

**Treatment of Urinary Infections by Ketogenic Diet**—Goodman points out that the ketogenic diet is indicated in initial or recurrent acute pyelonephritis or cystitis without acute obstruction, chronic urinary infection without demonstrable gross pathologic changes, chronic urinary infection associated with pathologic change demonstrable by roentgenography, urography or cystoscopy, urinary infection following operations, preliminary preparation for certain urologic operations, urinary infection following instrumentation such as the passing of catheters, sounds or cystoscopes and in urinary infection following gonorrhea, in the presence of inoperable neoplasms and in the presence of anomalies. The author obtained satisfactory results in twenty-two of thirty patients receiving the diet, five of which were outstanding cures. (1) chronic pyelonephritis, cystitis and prostatitis, (2) polycystic kidneys, (3) cystitis, prostatitis and chronic epididymitis, (4) chronic gonorrhea with prostatitis and (5) prostatitis with residual urine of 180 cc. Local treatments must be given for foci of infection. Vitamins are added to prevent metabolic disturbances. Should ketosis be too severe, alkalis and a small amount of orange juice or tomato juice should be given. Thin, cadaveric patients do not tolerate the diet. Patients on the diet lose from 4 to 10 pounds (1.8 to 4.5 Kg).

**Treatment of Hydrocephalus by Endoscopic Coagulation of the Choroid Plexus**—Putnam describes an endoscopic instrument with which it is possible to destroy the choroid plexuses within the lateral ventricles by means of electrical coagulation without removal of spinal fluid. He employed the procedure in seven cases of communicating hydrocephalus in infants and one of meningocele without hydrocephalus, relieving the bulging of the fontanels and decreasing the diameter of the head in all cases except one. There have been two deaths, which were due to intercurrent diseases and possibly are not to be attributed to the operation. The intra-cranial pressure was relieved up to the time of death in the two fatal cases.

**Endometrioma of Bartholin's Gland**—Duncan presents what he believes to be the first case of endometrioma of the gland of Bartholin. The patient complained of a hard, painful mass on the left side of the vulva, which had been trouble some for the past year and a half. The pain became worse

periodically at the time of each menstruation and decreased after the flow stopped. Four years before the present admission she had an acute inflammation of the gland of Bartholin, at which time the gland was incised and drained. The day following operation she began to menstruate. On examination a firm bluish nodule, 2 cm in diameter, was found at the site of the left gland. The nodule was not tender and could be moved about freely in the tissues of the labium. A diagnosis of endometriosis was made. The tumor was removed and on section presented the typical picture of endometriosis, photomicrographically. It seems tenable that following the incision and drainage menstrual blood containing living endometrial cells penetrated the site of the gland and produced the tumor.

**Treatment of Prolapsed Rectum**—Warren presents two cases of complete prolapse of the rectum in children, in which there has been no recurrence in three years. The following technic was used. Beginning at the apex of the protrusion a dental needle is plunged through the mucosa into the muscular coat of the protrusion and an injection of 4 or 5 minims (0.25 or 0.3 cc) of a solution of 4 per cent quinine and urea in 0.5 per cent solution of procaine hydrochloride is made. The needle is withdrawn, moved to the right half an inch, inserted again and the injection is made. This is repeated at one-half inch intervals until a complete circle has been made. Then one half inch away a new circle is started, the punctures staggered so that they will not be in a straight line. The circles of punctures are continued at one-half inch spaces until the anal margin has been reached. With the patient in the knee chest posture the mass is replaced. A heavy gauze pack is placed in the rectum, 8 or 10 inches of a 3 or 4 inch gauze bandage, being used with 1 or 2 inches of gauze protruding from the rectum to facilitate removal. The patient is then given one-fourth grain (0.016 Gm) of morphine and put to bed for from twenty four to thirty-six hours and given a liquid diet. At the end of that time an ounce of petrolatum is injected into the rectum with a glaseptic syringe and by gentle traction the gauze can be removed with almost no inconvenience to the patient. Nothing more is needed except to keep the patient in bed another twenty-four hours on a liquid diet.

**Methylene Blue in Localization of Perforated Peptic Ulcers**—Nisbet recommends methylene blue in abdominal emergencies in which a perforated peptic ulcer is suspected. The operating time is definitely shortened. There should be

less manipulation of the viscera if the distribution of the dye is observed. The dye is of definite value in a differential diagnosis. The diameter of the perforation is easily determined and, when the perforation is sealed by a plastic exudate, the stain shows the site of the original lesion and also whether or not further plastic surgery is required. During the last five years the author has had seventeen cases of perforation. In some the diagnosis was obscured by the inability of the patient to give an accurate history.

**Peptone Broth in Treatment of Ruptured Appendix**—Feagles and his associates have used isotonic peptone broth in the treatment of eight cases of ruptured appendix with peritonitis and one case of amputation, with apparent benefit. At present their procedure is to pour in about 100 cc of the broth before inserting a fenestrated split rubber tube drain and closing. On each subsequent day from 5 to 10 cc of the broth is injected into the drainage tube. The pus is examined at the time of operation and every day thereafter for organisms. The organisms disappeared from the discharge on the fourth to the sixth day. The temperature and the pulse were down to normal on the third to the fifth day. The drainage tube was shortened and out as a rule by the fifth day. Hospitalization time was much reduced and apparently complications were less frequent.

**Intrathoracic Changes in Tularemia**—Blumberg and Russell point out that clinical, roentgenologic and gross pathologic changes within the thorax in tularemia may be those of increase in hilus and bronchial lymph nodes, exudation, pneumonic consolidation, abscess formation, cavitation, vascular changes, necrosis, thickening of bronchial trunks, fibrosis and pleurisy with or without effusion. The microscopic observations are those of vascular changes, necrosis, and proliferation of fibrous tissue. Endothelial cells and mononuclear and polymorphonuclear leukocytes are seen. The Langhans type of cell is usually absent in the pulmonary lesions but can be found in the affected bronchial lymph nodes. Unexplained pulmonary and pleuritic conditions should always be investigated, as they may be tularemic in origin. Patients presenting intrathoracic complications may recover unless the condition has advanced too far. In order to avoid any hazard to the patient and that intrathoracic complications may be recognized early, a roentgenogram should be taken of every patient having tularemia.

**Amaurosis Following Application of Ethylhydrocupreine**—Griffey states that those who prescribe ethylhydrocupreine should be familiar with its dangers to the visual

pathways The toxic action is due to a spasm of the retinal vessels, causing ischemia of the retina Degenerative changes occur in the ganglion cell layers of the retina and, if severe, lead to ascending atrophy of the optic nerve fibers Depending on the severity of the reaction the final visual results grade from complete recovery, through relative or absolute scotomas and constricted visual fields, to complete and permanent amaurosis The toxic action of the drug on the visual apparatus may be due to drug idiosyncrasy in a susceptible person or to faulty elimination in one who is nonsusceptible The author reports a case of complete amaurosis in a patient having damaged kidneys, who received not more than 8 grains (0.5 Gm) of the drug by topical application to the pharyngeal mucosa

### Effect of Gamma-Ray of Radium on Wound Healing

—Nathanson treated wounds produced in fifteen dogs with varying dosages of the gamma-ray of radium at different time intervals with fixed distance and filtration to ascertain the effects of this type of radiation on the healing process Acceleration of healing was observed in those wounds which were exposed to small and moderate doses immediately after incision Retardation was noted in those wounds receiving higher doses Retardation of healing was noted in all wounds exposed to any dose of radiation twenty-four hours after incision, the degree varying directly with the dose When the wounds were subjected to varying doses forty-eight hours after incision, retardation effects were noted by the use of the higher doses and no change was seen with the smaller doses The retardation in healing did not interfere with the formation of a smooth scar

### Preoperative Preparation of the Dilated Stomach—

Orr and Curphey restore a markedly dilated stomach to normal size in an average of from four to six days by using the continuous gastric lavage with suction An indwelling Levine tube passed through the nose is suitable for this purpose At the beginning of such treatment it may be necessary to lavage the stomach through a large tube to remove particles of food and mucus too large to pass through a Levine tube With the nasal tube in place, the patient is urged to drink as much water as possible All water, secretions and gas are promptly removed from the stomach by continuous suction After a few hours of lavage, liquid will frequently begin to pass through a previously completely obstructed pylorus This may be demonstrated by the administration of a small quantity of barium sulphate Careful attention must be given to the maintenance of chemical, water and metabolic balance A study of the blood chemistry may indicate the need of sodium chloride Water, salt and dextrose should be given by vein or hypodermoclysis Since a loss of the gastric juice reduces the body chlorides, a daily check of the blood chloride content is advisable

### Culturing Bacteria Requiring Carbon Dioxide Tension

—Dickens points out that in 1932 the United States Naval Medical School began investigations of the cause of accidents in the navy incident to personnel entering compartments that had been closed for a long time The investigation was started with the knowledge that paints drying by oxidation depleted the oxygen content of the atmosphere, provided the compartment was closed prior to the drying of the paint The air obtained from compartments of ships that had been painted with linseed oil paint and closed for a considerable period was found to be markedly deficient in oxygen In the experiments conducted at this school it was found that small containers such as Erlenmeyer flasks, in which a small quantity of linseed oil had been placed, depleted the air in the flask of its oxygen content and further investigation determined that, if this oil was heated and the flask stoppered before the air had been allowed to cool, the oxygen content could be reduced to as low as 2 per cent within a few hours The oxidation was markedly accelerated by the addition of a catalytic agent (common commercial paint dryer) The final working method is as follows: The Erlenmeyer flask containing from 75 to 100 cc of linseed oil was heated, the air above the oil was displaced by carbon dioxide gas and the flask was stoppered with a rubber stopper containing a bent glass tube immediately connected to the rubber tubing from the culture tube The Stewart clamp was then opened and a partial vacuum was created when the hot oil cooled The carbon dioxide in the flask diffused across, and as the linseed oil absorbed the oxygen the bacteria began to grow when the oxygen-carbon dioxide tension became optimal The gas tension can be controlled, as the growth of an organism reaches an optimum, by closing the Stewart clamp and detaching the Erlenmeyer flask containing the oil Should the bacteria fail to grow further, after the flask has been detached, the oil may again be heated, more carbon dioxide added and the flask attached to the culture tube as before The growth may be thus accelerated from time to time, as the occasion warrants The materials necessary for this method of growing anaerobic organisms are the usual culture tubes containing the mediums to be used, two rubber stoppers in which a short piece of bent glass tubing has been inserted, an Erlenmeyer flask, small pieces of chemical rubber tubing, Stewart clamps, linseed oil, a good commercial paint dryer and a tank of carbon dioxide The author believes that this method of culturing anaerobic organisms is practical and can be applied in any laboratory

**Method for Determination of Bilirubin**—Van den Bergh and Grotepass describe an improved method for the determination of bilirubin in the serum by means of the diazo method. The first improvement is the colorimetric determination in monochromatic light by means of a dimming wire gauze, instead of the fluid for comparison which was formerly used. This instrument is standardized with azo-bilirubin, derived from chemically pure bilirubin. The second improvement is the prevention of the adsorption of bilirubin to the albuminous precipitate, which occurred when the old technique was followed. This result is achieved by adding, in suitable proportions to the serum, a mixture of reagent, diluted alcohol and a buffer.

**Antenatal Use of Quinine**—Buddee gave sixty-six primiparous and thirty-four multiparous women quinine hydrochloride during the last weeks of gestation. A series of the same number of primiparas and multiparas has been observed for comparison. It was found that quinine, given in small doses in the last weeks of gestation, acts as a general tonic and stimulant, and the patients feel well and are often improved. Idiosyncrasy is likely in a small proportion of cases, and its manifestations may include skin reaction and the onset of premature labor. There is no evidence to suggest any fetal toxicity or increase in fetal mortality and, apart from idiosyncrasy, little risk of premature labor. The effect of the drug on the duration of labor is of doubtful value. Inertia is certainly not eliminated.

Mental Deficiency Practice at Caterham Mental Hospital T Lindsay—p 397

**Action of Glycine in Schizophrenic Patients**—Reid observed the chemical changes in the blood and urine during the specific dynamic action of glycine in twenty normal subjects. The dose of glycine used was 22.5 Gm. per square meter of body surface. Six controls were given water instead of glycine. After glycine (average dose 38 Gm.) the aminonitrogen content of the blood reached its maximum near the end of the second hour. In the seventh hour it was usually less than 1 mg. above the fasting level, but there were considerable individual variations. Blood urea nitrogen increased slowly and steadily during the period of observation. The mean increase in the seventh hour after glycine was about 4 mg. per hundred cubic centimeters but the actual increase in a particular case appeared to depend entirely on diuresis and the urea excreted. Blood sugar decreased from about 10 to 15 mg. per hundred cubic centimeters after glycine ingestion but tended to approach the fasting level in the course of from six to seven hours. The non-dextrose reducing substances were not significantly altered. The nonprotein nitrogen fraction (nonurea and aminonitrogen) of the blood was increased after glycine administration. Nitrogen elimination was much increased after glycine. Approximately the excess urea nitrogen excretion during six hours of the postglycine period amounted to 0.23 of the nitrogen given as glycine. The total nitrogen of the urine (less the aminonitrogen and ureanitrogen fractions) was increased after glycine feeding. This was due either to increased elimination or to increased production in the tissues, or to both. Sulphate excretion after glycine was maintained at a higher level than was found for controls during the postabsorptive period. It appeared that the sulphate excretion provided a more reliable index of specific dynamic action than the nitrogen excretion during the period of observation in the experiments dealt with. The examination of schizophrenic subjects after glycine ingestion (average dose 32 Gm.) did not reveal any striking deviation as regards their blood and urine chemistry from the results in normal subjects. The character of the mean blood aminonitrogen and urine aminonitrogen curves suggested delay in the absorption of the ingested material as compared with normal. Blood nitrogen and urine nitrogen estimations were not significantly different in schizophrenic patients from normal subjects. Approximately the excess urea nitrogen excretion after glycine amounted to 0.21 of the nitrogen ingested as glycine. Sulphate excretion on the whole was less for schizophrenic patients than for normal subjects after glycine. Blood urea values in schizophrenic patients and in normal controls after the administration

of 15 Gm of urea in 100 cc were suggestive of delayed absorption, since the rise in the blood urea was slower in the former. The author considers the attempt to demonstrate variations in the specific dynamic action of foodstuffs or glycine by ingestion methods in psychotic patients is also unjustifiable, in view of the variations in the processes of absorption that have been demonstrated in both normal and psychotic subjects.

**Use of Histamine in Rheumatism**—Shanson and Eastwood studied the effects of histamine and thiohistamine in the treatment of seventy adult cases of chronic rheumatism and allied disorders. The series included examples of rheumatoid arthritis, fibrositis, osteo-arthritis, subacute rheumatism and gout. It was not possible to withhold other treatment (physical therapy) from these patients, nevertheless the results due to histamine could be easily recognized by the time relation which they bore to the injection. Histamine was given by subcutaneous injection. The solution was prepared in the strength of 1 mg of histamine acid phosphate to 1 cc of saline solution, and 0.5 per cent phenol was added as a preservative. The initial dose was 0.1 mg (i.e., 0.1 cc), and this was increased daily by 0.05 mg until definite improvement was observed. A satisfactory dose was usually found to lie between 0.1 and 0.5 mg. This dose was repeated two or three times a week and further increased if the response diminished. Thiohistamine was given by intramuscular injection and was found to be less potent than histamine. Histamine produced benefit in examples of all types of rheumatism, but a certain type of case was particularly amenable to this treatment, that is, the coexistence of impaired grip, the result of periarticular arthritis in the hand, with vasomotor symptoms. The response to histamine varied from patient to patient, and even in the same patient at different times. The following is a list of all the effects that were observed: flushing, relief of pain, increased range of joint movement, relief of vasomotor symptoms, sweating, headache, dizziness, drowsiness, increased appetite, a sense of well being, changes in blood pressure and temperature, and paresthesias.

**Clinical Application of Histamine in Rheumatism**—Mackenna presents the results he has obtained in rheumatism with histamine by ionization and massage. With the treatment the patient experiences an immediate relief from pain, either complete or partial, and can demonstrate a greater range of movement when previously there was restriction. This lessening of pain is always present and may last a few hours, a few days or permanently. In addition there is a feeling of local warmth and general well being. The undesirable results that must be carefully watched for include headache or a feeling of fullness in the head, tachycardia, a feeling of constriction in the chest with consequent breathlessness, burning and faintness, any one of which is an indication for the immediate cessation of the treatment. Treatment may be given daily. Histamine has a definite place in the treatment of fibrositis and neuritis, and in all chronic rheumatic disturbances associated with pain and limitation of movement. With histamine it is possible to cure fibrositis and neuritis completely and almost invariably to

decrease or remove pains of the joints in other suitable cases. The process of ionization with histamine requires unremitting attention during the whole of the sitting and, even more important, the tolerance of a given patient as to both time and milliamperage varies greatly from day to day.

\*Protective Action of Bayer 205 Against Trypanosomes of Man H L Duke —p 1336

**Action of Complex Carbamide Compound of Trisulphuric Acid Against Trypanosomes**—Duke states that a consideration of the evidence now available suggests that 1 A single dose of 1 grain (0.065 Gm) of complex carbamide compound of trisulphuric acid (germannin) given intravenously will protect a man for at least 113 days from infection by tsetse carrying cyclically *Trypanosoma rhodesiense*. 2 The administration of a second dose three weeks or more after the first enhances the protective effect of the compound. 3 Within certain at present undetermined limits the protective effect may be directly proportional to the number of doses given, although this point is not yet definitely settled. Three infected volunteers, all treated with complex carbamide compound of trisulphuric acid as soon as trypanosomes were first detected in the peripheral blood and each receiving six doses of 1 grain were protected against *T. rhodesiense* for 180, 182 and 190 days, respectively. 4 The natural sensitiveness of the mammal to the trypanosome plays an important part in determining the duration of the protection conferred by the compound, the more susceptible monkey receiving less protection per dose per kilo gram of body weight than the more resistant man. It is probable that the protection conferred by the drug is greater against *T. rhodesiense* than against *T. gambiense*. *Trypanosoma gambiense* is an established parasite of man, whereas research has shown that *T. rhodesiense* may in certain circumstances lose its pathogenicity to man. If, then, the resistance of man to *T. rhodesiense* is indeed greater than to *T. gambiense*, then this factor will in all probability tend to produce the effect suggested. It is also possible that *T. rhodesiense* is actually more sensitive to the compound than is *T. gambiense*. Strains of *T. rhodesiense* vary in their power to use man. The drug will be most effective against the weakly endowed strains supplementing the natural resistance of the host. *Trypanosoma rhodesiense* strain LX was strongly pathogenic to man. The author points out that the prophylactic injection of from 1 to 1½ grains (0.065 to 0.1 Gm) for each adult should be repeated every three months while exposure to infection continues.

**Immunization Against Diphtheria and Scarlet Fever with Combined Toxoid**—Tsen administered three doses of a mixture of four volumes of diphtheria toxoid lot 6 and six volumes of scarlatinal toxoid lot 1, both of which were prepared in the usual manner by the addition of 0.4 per cent of formaldehyde to the original standardized toxins and incubating at about 40 C until they were detoxicated, to 112 children who gave positive Schick and Dick reactions. The results show that ninety or 80.36 per cent, became Schick negative, sixty eight, or 60.71 per cent, became Dick negative and fifty-six, or 50 per cent, became both Schick and Dick negative. The batch of combined toxoid used contained only 4.8 Lf units of diphtheria toxoid and 12,000 minimal skin doses of scarlatinal toxoid per cubic centimeter.

Rational Indications for Phrenicectomy A Bonniot and J Foix—p 81

\*Abdominal Complications of Phrenicectomy Y J Longuet and C Launay—p 157

**Abdominal Complications of Phrenicectomy**—The abdominal complications of phrenicectomy are divided into early and late types by Longuet and Launay. After left phrenicectomy, some patients complain for several days of pains in the upper part of the abdomen at the level of the left hypochondrium. In other patients, vomiting may develop into a serious complication. In any case the early complications appear immediately after the operation and are almost always transitory. The most rational explanation is that they are attributable to traumatism of the intercostal nerve fibers which anastomose in the diaphragm with the terminal branches of the phrenic nerve. More important are the late complications that tend to develop months or even years after the operation. Their frequency varies in different reports, but, although not apparently rare, really serious cases are the exception. Left phrenicectomy is especially likely to produce these complications, owing to the location of the stomach on the left. Gastric disturbances predominate as a clinical symptom. In the mildest cases they consist of a constrictive and oppressive sensation or of postprandial distention in the left hypochondrium. Gaseous eructations and flatulence may accompany these symptoms. A frequent symptom is the sensation of rapid gastric repletion in the course of a meal. If the patient continues to eat, he becomes nauseated and belches and vomits. In serious cases, intractable vomiting occurs. Intestinal disorders also sometimes occur. Two principal roentgenologic images have been described: the markedly dilated stomach and the volvulus and folded stomach. Rare clinical variants are also described: signs of stenosis of the terminal segment of the esophagus, duodenal stenosis after right phrenicectomy and painful disorders of the iliac fossa and right flank. Treatment in mild cases is dietetic. It consists of small and frequent feedings. Gastric lavage is sometimes practiced with success. Prevention is more important. The authors believe that persons having ptosis and gastric ulcer are especially liable to abdominal complications, and phrenicectomy should not be practiced. Marked displacement of the heart to the left is an important contraindication.

\*Personal Modification of Crede's Method W Karnicki—p 437

**Uterovaginal Tamponade**—Bohler and Reiles discuss the role of uterovaginal tamponade in the hemorrhagic complications of delivery. Although granting the advisability of tamponade in selected instances, the authors advance several disadvantages to its indiscriminate use. In the hemorrhages of delivery treated by expression of the placenta, manual detachment, or massage, tamponade is superfluous if the uterus is well contracted. If the uterus after being packed with gauze does not react actively, it is technically impossible to fill it to the limits of elasticity and in any case this help would come too late. The hemostatic effect is due to reinstatement of good contractions rather than to the direct action of the tampon. The most important disadvantage of the tampon is the slowness with which the hemostatic effect is obtained. The authors lost five women in this way. Tamponade they feel, is a traumatizing method that may lead to serious lesions of the genital organs. As a substitute for this method of treatment, the method of uterine examination immediately after delivery as described in an earlier publication, and intravenous injection of hypophysis is proposed. As an intra-uterine intervention

often producing a vigorous massage of the organ, it constitutes an exciting agent of the first order, which often starts powerful contractions in the atonic uterus, rapidly returns the organ to a state of retraction, and stops hemorrhages. This action is not constant, however, and the intravenous injection of hypophysis is also advisable. In more than 200 intravenous administrations of hypophysis the authors observed no accidents. This method may be substituted for tamponade without any of the dangers inherent in the latter, with practically no mortality, with a slight morbidity and, especially, with a prodigious rapidity of action allowing the arrest of nonmassive hemorrhages in less than a minute.

**Modification of Crede's Method**—Karnicki's modification of Crede's method consists in producing a retroplacental hematoma and then the expulsion of the placenta without tearing. The procedure consists of four steps: 1 Search for the point of attachment of the placenta by palpating the region of the uterus asymmetrically enlarged (usually this is one of the horns of the uterus especially the right). 2 Periodic massage, practiced with two fingers of the center of this region until the contraction of the small massaged segment is obtained. This indicates the separation of the placenta and the creation of a retroplacental hematoma. 3 After the formation of the contracted area at the center of the softened portion of the uterus, the surrounding region is massaged until a symmetrical form is obtained indicating a complete placental separation. 4 Expression with the right hand on the segment previously massaged in order to avoid crushing the placental tissues. The hematoma alone is compressed in pushing this part in the direction of the uterine canal to give a favorable direction to the expulsive force. To avoid the production of a fold between the uterine body and the lower genital passages, the palm of the left hand is placed at the level of the pubis. It is useful but not necessary for an assistant to pull on the cord to direct the exit of the placenta. This procedure possesses the advantage of establishing the diagnosis of adherence. The author has used this method for four years and rarely practices artificial delivery any more. When internal manual intervention is necessary, a nonadherent placenta is never found.

Significance of Tuberculosis of the Aged in Campaign Against Tuberculosis M Kartagener—p 598

General Points of View on Pulmonary Tuberculosis C Schnetter—p 602

Trials with a New Gold Preparation in Pulmonary Tuberculosis W H Gomin—p 604

**Traumatic Tuberculosis**—Von Mejenburg discusses cases in which he rendered expert testimony on the traumatic character of tuberculosis. He concludes that traumatic tuberculosis is rare and thinks that complete responsibility can be talked of only in case of inoculation or vaccination tuberculosis, that is, when together with an injury of the skin a tuberculous infection takes place, or when an existing wound becomes infected with tubercle bacilli. In cases of this type not only should the preexisting tuberculosis be accepted but a differentiation should be made between isolated organ tuberculosis that does not produce hematogenic metastases, even under the influence of a trauma (the most characteristic form being chronic pulmonary tuberculosis), and the hematogenically generalizing tuberculosis that is characterized by dissemination and by tuberculous manifestations in various parts of the organism. In the latter form a considerable mechanical trauma may lead to a localization in the injured area, but presumably then only when accident and dissemination concur more or less.

**Tonsils as Port of Entry in Tuberculosis**—Schlittler relates that in ninety-eight patients with cervical lymphomas, suspected to be of a tuberculous character, but in whom pulmonary tuberculosis or tuberculosis of other organs could be excluded, the tonsils were removed and their examination revealed tuberculosis in forty-eight cases. Thus it appears that in case of a prolonged lymphadenitis of the neck, particularly at the angle of the jaw, a primary tuberculous disease of the corresponding tonsil may be suspected, especially when in

the region of the upper air and food passages there are no other causes detectable that would explain the swelling of the lymph nodes, and when the examination of the lung likewise remains negative. In addition to the subacute or chronic form of lymphadenitis, there is also one in which an acute swelling of the cervical lymph nodes at the angle of the jaw becomes manifest with the symptoms of an acute tonsillitis or peritonitis. However, the stationary behavior differentiates it from the swellings of lymph nodes caused by other infections. He thinks that primary tuberculosis of the tonsils is not as rare. There is generally no macroscopic change in the tonsil and only microscopic examination permits a diagnosis. It is nevertheless advisable to remove the primary focus, the tonsils, for this measure would prevent a further invasion of tubercle bacilli from the tonsils into the cervical lymph nodes and thus would lead to a more rapid cure of the tuberculosis of the cervical glands. The tonsils of these patients should always be subjected to microscopic examination in order to gain a better insight into the interrelation between primary tonsillar tuberculosis, tuberculosis of the lymph nodes and tuberculosis of the lungs. Physical and roentgenologic examination of the lungs should also be done.

**Functional Test of Reticulo-Endothelial System for Diagnosis of Osteo-Articular Tuberculosis**—Rabboni and Alberghina experimented with the congo red test on thirty patients having osteo-articular tuberculosis. Their technic is the following. About 8 cc of blood is aspirated from a vein of the elbow and poured into a centrifuge tube containing 1 cc of a 5 per cent solution of sodium citrate in physiologic solution of sodium chloride and, without removal of the needle, a 1 per cent solution of congo red is injected in the proportion of 1 cc for every 6 Kg of body weight. This is the dosage used by most authors in the congo red test. After intervals of four minutes and of sixty minutes, 5 cc of blood is aspirated from the other arm of the patient and put in tubes containing 1 cc of the solution of sodium citrate. The blood is centrifuged and the concentration of the color in the plasma is determined by means of the colorimeter of Hellge and by artificial illumination. These tubes are compared with the sample solution prepared from the plasma of the blood originally obtained, making a 1/10,000 solution of congo red. The authors found that the functional activity of the reticulo-endothelial system by means of the congo red test in various anatomoclinical forms of osteo-articular tuberculosis constantly shows a behavior parallel to the seriousness of the disease, in that there is a greater retention of color on the part of the cellular elements of the reticulo-endothelium in benign forms tending toward fibrosis, or beginning and slight retention in fungoid forms. In forms considered fibrosclerotic processes with a tendency to ankylosis, the congo red found in the circulation one hour after injection varies from 50 to 60 per cent, in beginning forms of hydrarthrosis from 60 to 77 per cent, in forms with cold abscess with or without fistulas, from 63 to 85 per cent, in fungoid forms from 74 to 95 per cent. Since there was a constant and gradual correspondence between the gravity or lack of gravity of the anatomoclinical system as tested by congo red, the authors feel authorized in attributing some value to this test in the qualitative diagnosis of this localization of the tuberculous infection.

**Surgically Important Localizations of Heterotopic Endometriosis**—Furst and Škorpil discuss the symptomatology and the pathology of surgically important sites of development of heterotopic endometriosis. These involve principally the navel, Poupart's ligament, the intestine and the urinary bladder. The authors describe three personal cases: (1) an endometrioma of the navel with a characteristic bleeding at each menstruation, (2) a recurrent endometrioma of the extraperitoneal portion of Poupart's ligament with invasion of the femoral vein, and (3) retrocervical endometriosis invading the rectum in which, during each menstrual period, there was an exacerbation of the intestinal symptoms and rectal menstruation. Because of a correct diagnosis and favorable location the authors were able to observe the endometrioma through a rectoscope. They were the first to describe the alterations in a rectal endometrioma provoked by the menstrual function as well as their disappearance after roentgenologic castration. In the histologic studies of their cases the authors found among the usual elements scattered elastic fibers, which they believe developed from the vessel wall. Tumor tissue excised repeatedly at menstrual periods showed histologic alterations corresponding to those of uterine mucosa.

**Diagnostic Errors in Connection with Tuberculosis of Mammary Gland**—Resnitzky states that tuberculosis of the mammary gland is rare. It occurs almost exclusively in women, with greater frequency in multiparas. The involvement is always unilateral, the right breast being the one more frequently involved. The author considers biopsy the most reliable method of diagnosis. Errors in diagnosis based on histologic studies of removed biopsy material are due to faulty technic in performing the biopsy. Biopsy pieces must be sufficiently large to permit examination of a number of areas as well as to include a zone of normal tissue. The author reports a personal case in which histologic examination of biopsy material revealed a structure closely resembling that of a squamous cell carcinoma. Histologic examination of the amputated breast revealed its tuberculous character.

**Treatment of Pressure Damage to Spinal Cord**—In arriving at an early diagnosis of a spinal cord lesion one should aim, according to Kulenkampf, at a recognition of the existence of damage to the cord rather than at determination of the nature of the lesion. The purely anatomic diagnosis based on the recognition of involvement or paralysis of definite nervous elements is not sufficiently refined to permit of an early diagnosis. When such a diagnosis is possible the outlook for a cure is rather poor. The living organism reacts to damage by a complicated interplay of adaptation and correction mechanisms for which a definite anatomic pattern does not exist. The recognition of these changes, a functional diagnosis, should precede the purely anatomic one. Variability is a characteristic feature of these early functional changes. There may be noted an early fatigue of the legs or arms, a change in the psychic attitude toward a limb, and insignificant circulatory changes giving rise to cold or to warm feet. There may be noted abnormal pigmentation, sweating and abnormal growth.

of hair or of nails. The patient may develop a clumsiness in movements and a tendency to stumble or to drop objects. On physical examination there are found, as a rule, lively reflexes which are of no diagnostic value and, occasionally, a doubtful or a strongly suggestive Babinski sign. A definite impairment in power in the same and similarly developed muscle groups is quite suggestive. Simultaneously with Dandy the author called attention to the so called coughing and sneezing symptom, the development of a severe pain on coughing or sneezing. There may be limitation of the movements of the spinal column due to associated alterations in it, or a slight gibbus may be present. It is essential to get all the information possible from the simple spinal puncture. Xanthochromia, for example, is characteristic of a tumor, while the Queckenstedt test furnishes information as to the existence of an obstruction. The latter, however, is not always reliable. The diagnosis of the level of the lesion is arrived at through roentgenography after the injection of iodized sesame oil. The author never injects more than 1 cc. of this substance and did not see any damage arise from its use. He stresses the necessity of taking stereoscopic views of the cord after the injection of iodized sesame oil. These, not infrequently, give a remarkably clear localization and delineation of a shadow caused by the tumor. This is a distinct advance over the method of level localization by the purely neurologic examination. The iodized sesame oil roentgenographic method, however, is not entirely free from errors. In the presence of arachnoiditis there may be a definite obstruction to iodized sesame oil filling, which may be erroneously interpreted as due to tumor. The author operated in two such cases. Stereoscopic and lateral views of the spinal column are essential in recognition of associated scoliosis, lordosis or slight gibbus. Intercostal neuralgia, lumbago or sciatica may be caused by pressure of the tumor. A spinal puncture is therefore indicated in their presence. The differentiation of an extradural or intradural tumor can be made in many cases on the presence of neurologic signs. In the operative treatment the author emphasizes the advantages of local anesthesia, of the lateral position, preferably on the left side, of slow, painstaking exposure and of omission of drainage. Operations for recurrence are difficult but are worth while.

**Hyperparathyroidism and Related States**—Bauer reports the further developments in the case in which F. Mandl removed in 1926 an adenoma of the parathyroid for the cure of osteitis fibrosa cystica generalisata of von Recklinghausen. This was the first operation of the kind to be performed for the cure of von Recklinghausen's disease of the bones. The result was good, and the formerly bedridden patient was able to walk without pain at the end of two months. The improvement lasted six years. In 1932 the patient was admitted to Bauer's clinic because of the return of the original symptoms of pain on movement of the extremities and because of progressive deformity of the skeletal frame. While under observation the patient developed renal colic caused by calculi in the right renal pelvis. The blood calcium was slightly increased (125 mg per hundred cubic centimeters), but the phosphorus was lowered (25 mg per hundred cubic centimeters). The calcium balance was decidedly negative because of the abnormally high amounts of calcium excreted in the urine. There was a lowering of electrical irritability of muscles and nerves. The symptoms mentioned were significant of a return of a state of hyperparathyroidism possibly due to a formation of another hyperfunctioning parathyroid tumor. Roentgen irradiation of the pelvis, the femurs, the tibiae and the region of the parathyroids was ineffective. A secondary operation was undertaken by Mandl, but in spite of painstaking search no tumor of the parathyroid was found. A subtotal thyroidectomy was performed. An examination of the removed tissue by the pathologist Professor Sternberg revealed one normal parathyroid body on the surface of the thyroid and another normal body within the thyroid. There was no improvement after the operation. At the end of two months the patient was in worse condition than before the operation. The blood calcium did not sink, the inorganic blood phosphorus remained unaltered and the excretion of abnormally high amounts of calcium in the urine persisted. The author is of the opinion that there exists a hyperfunctioning adenoma of the parathyroid which because of inaccessible location, was not found.

**Paget's Disease of Bones and Parathyroid Tumors**—Kienbock states that the consideration of the entire course of Mandl's case convinces him that the original diagnosis of Recklinghausen's osteitis fibrosa was erroneous. He believes that to be a case of Paget's disease of the bones associated with a rather unusual complication of a parathyroid tumor and irregularly arising porosis, softening, bending and fragility of the bones accompanied by pains rarely observed in this condition. The roentgenologic appearances of the bone changes are characteristic of Paget's disease. Diffuse thickening, malacic bending, alternating porosis and thickening, and involvement limited to the epiphyses and immediately adjacent part of the shaft rather than of the shaft alone are characteristic of Paget's disease. There was an absence of large cysts such as are seen in Recklinghausen's disease. The author regards the occurrence of the parathyroid adenoma here as a coincidence rather than the cause of the condition. The mild state of hyperparathyroidism, as suggested by the studies of blood chemistry in the case, is not infrequently seen in the porotic form of Paget's disease. Additional evidence is to be seen in the fact that a sister of the patient, aged 49, was found to present a clear cut clinical and roentgenologic picture of Paget's disease. Familial occurrence of Paget's disease is not uncommon, it has not thus far been described in connection with Recklinghausen's disease. The error in the original diagnosis arose because in Germany at that period the existence of two separate entities was not appreciated. Nevertheless the author feels that Mandl's work contributed much to the subject of Recklinghausen's disease. The author is of the opinion that bone changes develop first and that these are followed by the development of hyperparathyroidism. The latter influences unfavorably the progression of skeletal changes and retards regenerative processes. Since the operation by Mandl a number of similar operations have been performed the world over with success in cases of osteitis fibrosa of Recklinghausen.

**Method for Demonstration of Occult Hemorrhages**—Boas emphasizes that, without extracting from the feces all substances disturbing the peroxidase reaction that is, all anti-catalytic substances, correct results cannot be expected in the examination of the feces for occult hemorrhages. Further, he points out that all peroxidase reactions known thus far are extremely volatile, owing to the further oxidative transformation of the reaction products. This is especially true of the benzidine test. A further disadvantage of the benzidine as well as of the guaiac tests is the slow development of the reaction, particularly if the blood content is slight. This retardation may lead to a negative interpretation. The author describes a new peroxidase reaction which is in many respects superior to the older methods. He employs as reagent 2,7-diamino-fluorene-hydrochloride (called for short 'fluorene reagent'), it was first introduced as a reagent for persulphates and blood pigments by Schmidt and Hinderer. This reagent proved more sensitive than benzidine. Since the aqueous solution of 2,7-diamino-fluorene-hydrochloride was not sufficiently stable, the author employed a solution in concentrated acetic acid. He found that a 0.2 per cent solution of the reagent in 50 per cent acetic acid was the most suitable. The test is made in the following manner. A small amount of feces is placed into a porcelain dish, pure acetone is poured over it and after repeated shaking it is left standing for from five to ten minutes. After the acetone has been poured off, the smear is dried by shaking it. Then 5 cc of absolute alcohol and ten drops of glacial

acetic acid are poured over it and it is mildly shaken and then left to stand. The alcohol is poured off into a clean test tube and from three to five drops of the reagent and the same amount of a 3 per cent solution of hydrogen dioxide are added. If there is a considerable amount of blood pigment, a green to blue coloration sets in after several minutes of shaking. If kept in a dark place the color remains unchanged for twenty-four hours or longer, when it changes to olive green. The greater the amount of hematin, the more intense is the coloration and vice versa. If the hematin content is slight, the reaction becomes manifest only after from ten to twenty minutes, if it is entirely absent, there is no green coloration at all. The author further describes a more complicated modification, in which the colors are more vivid and the product of the reaction can be kept for longer periods.

**Hypophyseal Sex Hormone in Urine of Old Men—**Following a review of the literature on the behavior of hypophyseal sex hormone in the urine of old women, Kukos reports his studies on the urines of seventeen old men, aged between 70 and 84. The urine was examined not in the native condition but in a fivefold concentration. The test object was the same as in the Aschheim-Zondek test. The estimation of the outcome of the test was based on the microscopic examination. A tabular report of the results of the test indicates that the vagina never showed a positive reaction and that all positive reactions were detected by the microscopic examination of the ovaries. An increased elimination of the hypophyseal sex hormone could be detected in only six out of seventeen cases, and in four of these six the reaction was weak. The author concludes from this that the elimination of the hypophyseal sex hormone is increased in only a small percentage of aged men. He is unable to give an explanation of this phenomenon.

**Changes in Blood Distribution Caused by Changes in Position—**Ude studied the temporary course of fluctuations in the fluid distributions within the body by means of an apparatus resembling Mosso's scale. He found that when a young healthy adult is placed on the scale while lying horizontal and on his back there is an increase in weight toward the head for approximately thirty minutes. This 'shifting time' is longer when the test is made toward evening than when it is made in the morning. If the person has been lying down for from sixty to ninety minutes previous to the test, the erect posture of several minutes' duration does not produce a shifting in the center of gravity, but after approximately ten minutes of standing the scale indicates again an increasing heaviness toward the head shortly after the person has been placed on it in the horizontal position. The shifting time is now approximately proportional to the time of standing. The author assumes that this shifting in weight is due to the fact that while the person is standing the blood sinks into the lower extremities and that it flows back again when he is reclining. He thinks that on the basis of these observations it may be possible to estimate conditions of incipient cardiac insufficiency, because in persons with such disorders the time of shifting and probably also the quantity of shifted fluid differ from those in normal persons.

**Pathogenesis and Therapy of Nursling Toxicosis—**Among twenty-eight cases of nursling toxicosis, Csapó and Kerpel-Fronius observed only one that could be considered a pure alimentary intoxication, in all others an infectious focus could be demonstrated. To be sure, in most cases the nutri-

tion was likewise faulty. They give the history of one case of a parenteral toxicosis (otitis and mastoiditis) with a subsequent intestinal disturbance. They think that the mastoiditis was the most important factor in the etiology of the toxicosis, but it was not recognized, because of lack of symptoms. However, the unrecognized focus continuously discharged bacterial toxins into the blood stream, thereby impairing the parenchymal organs and reducing the tolerance to such an extent that even feeding with two-thirds milk presented an overburdening of the intermediate metabolism. The increased elimination of water led to exsiccosis. The quantity of urine was reduced, the elimination of the nitrogen containing waste matters became insufficient and the rest nitrogen of the blood increased. The elimination of the phosphates and of the organic acids that are produced in larger amounts was disturbed. The organic acids and to a certain extent also the phosphates reduced the bicarbonate, and a decompensated acidosis developed. By way of the gastro-intestinal tract, loss of chloride took place, which manifested itself in a hyposalemia. The authors think that the reported case is the most frequent type of parenteral toxicosis. As the most characteristic aspect of the intoxication, they consider the disturbance in consciousness and the deficient oxidation. In the subacute cases the disturbance in consciousness may be absent. The treatment of enteral and parenteral toxicoses, the authors generally begin with gastric lavage. To counteract the acidosis and to stimulate the cardiac action, they administer intravenously 50 cc of a 4 per cent solution of sodium bicarbonate and 20 cc of a 20 per cent solution of dextrose. In case of a severe acidosis the injection is repeated after twelve hours. Orally the child receives for from twenty-four to thirty-six hours only tea (sweetened with gluside) and Ringer's solution (1/3). The authors consider it inadvisable to let the patients fast longer than thirty-six hours, since a prolonged fast may increase the acidosis. After the tea pause, feeding with human milk is begun, the quantity being gradually increased. In case of hyposalemia intravenous administration of sodium chloride (4 per cent solution) is advisable. However, this measure can be taken only if careful chemical tests have been made, for a hyponatremia does not always present a chloropenia. The most important factor of the treatment is the removal of the bacteriotoxic factor. In enteral toxicosis the solution of this problem is difficult because of the inadequacy of specific serotherapy. The serum of dysentery is effective only in rare cases. Repeated blood transfusions are effective in only a few cases. In conditions in which the infectious foci are amenable to surgical treatment, the problem is comparatively simple.

**Action of Apple Diet in Diarrhea—**Fasold shows that the efficacy of the raw apple pulp in diarrhea has been ascribed to various factors to the mechanical cleansing process by the bulky matter, to the toxin adsorbing action of the colloids, and to the sedative and tanning influence of organic acids and of the tanning substances. Without disregarding the sedative and astringent action, the author believes that the therapeutic action is largely due to the mechanical and adsorbing factors. Thinking that cellulose is an important factor, he has treated diarrheal disturbances in children by giving them a suspension of cellulose. He observed that the stools showed almost the same changes as are observed during apple diet. He concludes from this that the adsorptive and mechanical actions of cellulose are mainly responsible for the good results obtained with the apple diet. Further, he describes the studies made by Malyoth, which indicated that the curative physicochemical properties of the raw apple pulp are primarily the result of its pectin content. The author thinks that his observations and those of Malyoth complement each other and concludes that the two colloid groups pectin and cellulose are responsible for the efficacy of the raw apple diet in diarrheal disturbances.

**Type of Pneumococci in Children—**Joppich reports the type distribution in pneumococcal infections during childhood. He found that in infections with the  $\alpha$ -group of pneumococci the number as well as the severity of disease processes predominates over those that develop in infections with the fixed types of pneumococci. The pneumococci of the  $\alpha$ -group are the most frequent causal agents of all types of localized pneumonia and their complications which develop during childhood. Moreover, the majority of cases of meningitides of

childhood are likewise caused by them. However, in lobar pneumonia with its complications and in pneumococcal peritonitis, types I and II of pneumococci are generally found. But since in children the lobar pneumonias are of less importance (as regards numbers as well as prognosis) than the localized pneumonias, the types I and II are of secondary significance. The author observed also that the pneumococci of the  $\lambda$  group may lead to serious disorders out of a state of complete health. He found that the mortality rate of children is much higher after infections with the  $\lambda$ -group of pneumococci than after infections with types I to III.

**Treatment of Alimentary Intoxication with Intravenous Drop Infusions.**—Schmiedeberg reports that at the children's clinic in Tübingen the drop infusions recommended by Karelitz and Schick were introduced into the treatment of alimentary intoxication of infants. The regulations were strictly adhered to, that is, Ringer's solution with 5 per cent dextrose was infused into the vein of the arm, so that within twenty-four hours the child received from 100 to 125 cc for each kilogram of body weight. Moreover, in accordance with the directions of Schick the children were given before onset of the drop infusion 100 cc of a 5 per cent dextrose-Ringer's solution into the sinus longitudinalis or into the already exposed vein of the arm, into which the cannula for the continuous drop infusion was then inserted. Some of the children were given several infusions of citrate blood (from 70 to 100 cc). The drop infusion was continued for several days. During the first thirty-six hours the children were given no food. The dryness of the oral cavity was counteracted by giving some tea. Cardiac remedies were given every two hours. At the end of the thirty-six hours, food was given in small quantities. The author points out that Schick obtained favorable results with this method in that he reduced the mortality from over 60 to approximately 15 per cent. Her own results, however, were not this favorable. Numerical comparison of former therapeutic results and of those obtained with the Karelitz-Schick method revealed that in the uncomplicated cases the mortality was the same, whether drop infusion or the older methods were used. In the complicated cases the mortality was even slightly higher after the drop infusion. She thinks that the difference in the patient material may explain why she did not obtain the same favorable results with drop infusion as did Schick and Karelitz. She treated only severe cases of alimentary intoxication with this method. She further concedes that although numerically she was not able to demonstrate the superiority of the drop infusion over other treatments, at the bedside she nevertheless gained the impression that in some of the cases the drop infusion was of distinct advantage.

**Roentgenoscopy of Vermiform Appendix.**—Krenn used roentgenoscopy of the appendix in cases in which chronic appendicitis was suspected and which presented obscure symptoms of the gastro intestinal tract. A tabular report shows the results of the roentgenoscopy in 234 cases. In 117 of this number an operation was performed. In 86 of these 117 the appendix had not been demonstrable. Only 9 approximately 10 per cent were found to be free from changes. All appendices in which roentgenoscopy revealed filling with contrast medium but in which the filling showed abnormalities (short filling adhesions pressure points) were found to be diseased. Only 9 per cent of the appendices the roentgenoscopy of which had revealed signs of chronic appendicitis were free from pathologic changes. The high number (33 per cent) of erroneous diagnosis of chronic appendicitis before the introduction of roentgenologic examination has been reduced to 9 per cent.

\*Etiology of Amyotrophic Lateral Sclerosis S Dawidenkow—p 346

**Creatinine Content of Cerebrospinal Fluid.**—Lickint examined 500 specimens of cerebrospinal fluid by means of the calorimetric method suggested by Folin. He determined the normal creatinine content to be between 0.5 and 1.52 mg per hundred cubic centimeters. Within this normal range the creatinine content of the cerebrospinal fluid amounts to from 50 to 77 per cent of the serum values. In meningitis a complete equalization may take place between the creatinine content of the cerebrospinal fluid and that of the serum but in renal diseases the difference is generally increased because of greater retention in the serum. In various types of renal diseases (102 cases of acute and chronic nephritis and uremia) increases were usually observed, but the creatinine content of the cerebrospinal fluid did not always go parallel to its renal nitrogen content. The highest creatinine content of the cerebrospinal fluid amounted to 15.6 per hundred cubic centimeters. In fifteen cases of syphilis with a negative reaction in the cerebrospinal fluid the creatinine values were always normal, but eight out of thirty-three cases of metasyphilis or cerebrospinal syphilis showed a slightly increased creatinine content. Of the cerebrospinal fluids of sixty-seven patients with concussion of the brain, six showed a slight increase, while all other cases of encephalitis, meningism, epilepsy, hydrocephalus, multiple sclerosis and cerebral tumors had normal values. Of forty-two patients with meningitis only fifteen showed increases up to 2.44 mg per hundred cubic centimeters, the increase being somewhat more pronounced in epidemic than in tuberculous meningitis. The author concludes that an increase in the creatinine content of the cerebrospinal fluid has neither a differential diagnostic nor a prognostic significance.

**Etiology of Amyotrophic Lateral Sclerosis.**—Dawidenkow stresses that the familial amyotrophic lateral sclerosis of children and young persons should not be identified with the amyotrophic lateral sclerosis of adults, for a familial accumulation of the disorder in adults has not been observed as yet. The infantile form of the amyotrophic lateral sclerosis is not a uniform group, for in some cases it seems to be inherited according to the dominant and in others according to the recessive type. Moreover, there are cases in which the bulbar and spastic symptoms are only a part in a much more complicated symptomatology, then there are cases in which the atrophies are developed only in a mild form, in others the amyotrophy may have an uncharacteristic localization or the bulbar symptoms may be absent. However, in some instances the familial form occurring in children presents almost the same symptomatology that is observed in adults. The author shows that, in the search for the etiology of the amyotrophic lateral sclerosis in adults numerous factors have been considered. He mentions physical and psychic traumas, poliomyelitis and syphilis, and he points out that it has been considered as an abiotrophic systemic disorder. Since the investigations on most of these factors led to no definite conclusion, he decided to resort to the genealogical method. The study of ten genealogical trees revealed to him that in the families of patients with amyotrophic lateral sclerosis there is a considerable accumulation of constitutional anomalies of the nervous system, which become manifest primarily in abnormalities of the tendon, periosteal and cutaneous reflexes. These anomalies in the reflexes may be a weakening, a complete abolishment and an increase, or these various forms may occur together. However, there are approximately as many members of the families who are free from the reflex anomalies. The hereditary transmission of the reflex anomalies takes place according to the dominant type. The author concludes that his studies proved the existence of a hereditary component in the etiology of amyotrophic lateral sclerosis, but further studies will be necessary to solve the problem completely.

\*Especially Filtrable Form of Tubercle Bacilli P C Flu—p 3019

\*Spontaneous Recovery of Testicle Injured by Estrin Through Gonadotropic Hormone S E De Jongh and E Laqueur—p 3030

**Filtrable Form of Tubercle Bacilli**—Flu demonstrates that filtrates of tuberculous material made with Chamberland porcelain filters L2 and L3, being free from the test microorganisms mixed with the material to be filtered, do not produce any signs of classic tuberculosis or of the so called ultravirus tuberculosis. This would suggest that the germ is not filtrable. The author takes exception to Van Densen's criticism of the validity of his observations. No one can ever be sure that a filtrate made from a suspension of bacilli through the Chamberland L3 filter does not contain any bacilli. This is all the more true of the L2 filter. According to Van Densen, a large number of acid-fast bacilli are found if the filtrate is injected intraperitoneally into the guinea-pig. Acid-fast bacilli are sometimes found in peritoneal scrapings, provided the animals are dead within five to seven days after injection. It is striking that the acid-fast bacilli from the lymph nodes as well as from the peritoneum are not found in cultures and that sometimes through injections of the lymphatic fluid in guinea-pigs typical tuberculosis may be produced. The postmortem picture of the guinea-pig injected with the so-called tuberculous ultravirus is not described by every investigator in the same way. Although they all declare that no ulcer appears on the site of the subcutaneous injection some describe regional swellings of the lymph nodes with the presence of acid-fast bacilli, while others describe as the only symptoms swollen bronchial lymph nodes with or without individual bacilli. Some describe infiltrates in the internal organs, especially in the lungs, while others declare that they remain normal. In many cases the ultravirus was believed to be present because in injected animals every trace of pathologic change, aside from the slightest swelling of the bronchial lymph nodes, was absent and in no way could the acid-fast bacilli be developed from the supposed ultravirus forms. The author found that injections of acetone extracts from tubercle bacilli have an activating effect on a tuberculous infection of the guinea-pig only if free acetone is still found in the suspension of the extract to be injected. Only when the filtrates are free from bacterial elements can the tuberculous process in guinea-pigs be activated through injections of such filtrates mixed with acetone extracts. There is no proof that these injections really activate an ultravirus. But even in injection with a slight number of such virulent bacilli it happens, though seldom, that the infiltrate does not form on the site of injection and that it does not ulcerate. The former phenomenon happened once, the latter twice in thirty-two guinea-pigs. In injecting a small number of virulent bacilli the author found as the only symptom of tuberculous infection indurating glands, in which after an investigation of several hours some acid-fast bacilli were found. He could not find any proof of the existence of a tuberculous ultravirus. Perhaps everything that is regarded as the result of an infection with ultravirus may be attributed to the fact that, during filtration, a few tubercle bacilli of weak virulence passed through the filter. Filtration tests with Chamberland L2, L3 or even with other filters cannot solve the question of whether a tuberculous ultravirus is present or not.

**Spontaneous Recovery of Testicle Injured by Estrin Through Gonadotropic Hormone**—De Jongh and Laqueur state that the size of the testicle is no measure of its endocrine activity. Testicles of young animals treated with the gonadotropic hormone complex from the urine of pregnant women, by which treatment their hormone production is selectively stimulated, are hardly or not larger than those of untreated controls. The power of the gonadotropic hormone complex to cause a discrete growth becomes evident in testicles that are artificially made to regress by a treatment with estrin. In this case their weight is restored more completely by the gonadotropic hormone complex than without it. Far greater

is the influence of the gonadotropic hormone complex on the development of Leydig's tissue of the testicle and on the size of the other male organs, measured in this case by the seminal vesicle.

\*Atypical Muciparous Cancers of Stomach ('Linitis Plastica' Krukenberg's Tumor) L Kreyberg—p 729

**Investigations of Bones of the New-Born**—Toverud's material comprises 100 necropsies in new-born infants, of whom forty-seven were full term, forty-three premature, and ten twins. Chemical analysis of the same portion of the fourth rib and of the parietal bone in these cases showed a variation in the total ash content and in the calcium content, depending partly on whether or not the mother's diet during pregnancy had been deficient and partly on whether or not the child was born at term. Histologic studies of the parietal bone, rib and jaw in the first twenty-five necropsies disclosed somewhat enlarged osteoid zones and small osteoblasts with scanty intracellular spaces, especially in premature infants and those born of mothers receiving an insufficient diet during pregnancy. The author states that early postnatal craniotabes and early deformities of the jaw are direct consequences of a congenital osteoporotic condition and that this condition increases the tendency to the development of rickets.

**Intestinal Rupture in Hernia Without Incarceration**—In Røvig's patient, a man aged 69, having an inguinal hernia, rupture of the intestine in the hernial sac occurred after a fall from the height of a meter. The clinical picture was that of diffuse peritonitis. Roentgen examination revealed a perforation in the gastro-intestinal tract. Laparotomy and suture of the ruptured intestine, done about eight hours after the injury, were followed by recovery. A grave complication due to the spinal anesthesia, in the form of cessation of respiration, which set in during the intervention, was successfully treated by placing the patient in the Trendelenburg position and applying artificial respiration for about an hour, with 10 cc of a 25 per cent solution of pyridine betacarbonic acid diethylamine and 1 cc of epinephrine intravenously.

**Bone Tissue After Roentgen Irradiation**—Dahl irradiated the tibia and femur in young rats, which were then killed at regular intervals. A densification of the irradiated bones, seen as early as three hours after irradiation, became closer during the days following. In a second series, irradiated in the same way, vital staining with alizarin showed intensified coloration on the irradiated side beginning eight hours after irradiation. In a third series, in which carmine was injected two or three hours before the animals were killed, the skin reacted with increased exudation after eight hours following irradiation, and reduced circulation in the bone tissue was demonstrable as early as two days after irradiation. The experiences with alizarin are thought to show that the early densification seen in the roentgenograms is due to deposit calcium.

**Atypical Muciparous Cancers of Stomach**—In the three cases of cancer of the stomach of the leather bottle type and one of cancer of the gallbladder with metastases of Krukenberg's type to the ovaries, the tumor cells appeared as single cells or in small groups and produced mucin, mostly contained in intracellular vacuoles. As the cells tend to produce a marked fibrosis reaction and often appear in limited number, especially in the metastases, and as the metastases often give clinical symptoms before the primary tumor, diagnostic errors are frequent in this form of cancer. However, staining the specimens with mucicarmin, Kreyberg says, gives a characteristic picture and facilitates a correct diagnosis.

## THE UNDERGRADUATE TEACHING OF GASTRO-ENTEROLOGY IN AMERICAN MEDICAL SCHOOLS

CHAIRMAN'S ADDRESS

ALBERT F. R. ANDRESEN, M.D.  
BROOKLYN

The question whether gastro-enterology is a specialty or whether the care of diseases of the digestive tract and nutrition should be left entirely to the internist is one that has caused much controversy. In this connection it must be realized that the properly trained gastro-enterologist must be first a competent internist and must in addition have devoted much time to a special study of gastro-enterologic subjects, including the basic sciences, physiology, biochemistry, pathology, laboratory work, roentgen diagnosis and nutritional problems. The large numbers of clinicians applying for admission to postgraduate courses in gastro-enterology wherever they are presented is evidence of the importance of the subject and the lack of information in regard to it. The difference in results obtained in the treatment of gastro-intestinal disorders by the gastro-enterologist as compared with the general internist is so marked that the medical profession in general has long recognized the value of special care in these diseases, and it is to be hoped that soon even the general internist will cease to be prejudiced against this specialty. With the much less important and no more technical branches of internal medicine, neurology and dermatology, recognized as specialties, it is strange that gastro-enterology should be so generally unrecognized.

The prejudice against the gastro-enterologist has, unfortunately, projected itself into the medical schools, where prejudice and petty jealousies are so much to be deplored. It has resulted in a neglect of the teaching of subjects pertaining to the gastro-intestinal tract even in the early, preclinical years, where gastro-intestinal physiology today receives entirely inadequate attention and the student's time is largely wasted in the intensive study and contemplation of nerve-muscle reactions and abstruse biochemical problems.

One of the most important studies entered into by the Commission on Medical Education, organized in 1925 by the Association of American Medical Colleges, the final report of which was published in great detail in 1932 in a book of 600 pages, is the study of the frequency of occurrence of various symptoms as determined by the tabulation of the chief complaints of large numbers of patients applying for care in hospitals and their clinics, industrial clinics and the offices of general

practitioners in all parts of the country, supplemented by the study of the nature of disabling illnesses, the causes of death and the observations in health examinations such as school and factory surveys and the draft. A few sample tables taken from this book are shown in the accompanying tables, which have been chosen as being representative of the average. A study of the relative frequency of the chief complaints or illnesses of patients in ten separate studies presented in the tables of this book shows that gastro-intestinal complaints average between third and fourth places in relative frequency, being exceeded regularly only by minor surgical conditions, infections of the upper respiratory tract and venereal diseases. Logically, therefore, a medical education should aim to prepare a student adequately to handle these most important conditions. Yet what does one see in the average curriculum? The first two, preclinical, years are spent largely in the study of technical problems, taught in many schools by experts who are not physicians, and in most cases not only not correlated with clinical teaching but not even of value to the student in his subsequent study of clinical medicine, and the clinical years often devoted to intensive courses in some less important phases of internal medicine, with an entirely inadequate consideration of problems pertaining to digestive diseases.

In a questionnaire recently sent to the eighty-five class A medical schools in the United States and Canada, sixty-eight sent complete answers to a list of six questions propounded. Eight of the schools answering were so-called two year schools, giving only the preclinical course, and the authorities of these schools emphatically disclaimed any attempt at correlation between their teaching and that of clinical gastro-enterology. Of the sixty regular schools from which answers were received, only thirty-five, or 58 per cent, stated that there is such a correlation in their courses in the first two, preclinical, years. Only three schools were listed as presenting clinical lectures on gastro-enterology in their preclinical years. Is not this neglect of gastro-enterology surprising when it is realized that preclinical studies include biochemistry, which covers the study of digestion and nutrition, of physiology, the most interesting phase of which is undoubtedly a study of the digestive processes, of bacteriology, with the most prolific culture medium provided by nature in various parts of the digestive tract, and of pathology, the practical application of which consists largely in the diagnosis of tissue specimens or tumors removed from the gastro-intestinal tract? A survey of the work of the schools failing to show any such correlation between clinical and preclinical instruction shows that these are the schools in which not only is there no separate department for the teaching of gastro-enterology but in which the teaching of gastro-enterology is considered a relatively unimportant part of the course in medicine.

Of the sixty schools answering the questionnaire, only six, or 10 per cent, reported that they have a separate unit for the teaching of gastro-enterology. In four of these schools there is an established chair of gastro-enterology and the professor of this department has a staff of competent assistants giving a properly coordinated course in his subject, including the laboratory, clinical and roentgenologic phases of the work, as well as practical instruction in dietetics. In two schools a similar course is supervised by a clinical professor of gastro-enterology and an individual designated as "clinical professor of medicine (gastro-enterology)," respectively. In the other fifty-five schools the instruction in gastro-enterology is given by the department of internal medicine as a part of its course, the titles of the instructors ranging from professor to instructor in medicine. In more than a score of these schools these teachers are nationally known gastro-enterologists, but in most instances the time allotted to them is insufficient

The interpretation of roentgenologic observations constitutes a very important part of gastro-enterologic diagnosis. An inquiry regarding the teaching of this subject was therefore included in the questionnaire. All of the sixty schools are attempting to teach something about gastro-enterologic roentgen diagnosis, the roentgenologist being the teacher in fifty-six, or 93 per cent, of the schools. In six schools the gastro-enterologist, and in five the internist, is collaborating with the roentgenologist in this instruction, and in two the gastro-enterologist alone is the one to cover this subject. In one school a physical therapist is designated as the one to teach this important branch of diagnosis. In most schools this instruction is haphazard, with no definite time devoted to it.

If there is one subject, aside from gastro-enterologic diagnosis, about which the average general practitioner is very poorly informed, it is the subject of dietetics. Most of the diets prescribed for patients are based on superstition, on individual fancies, on information obtained from literature advertising freak food products or merely on the simple principle that the food an ailing patient enjoys and has been in the habit of eating must be bad for him and should be forbidden. Such freakish and unscientific diets as are broadcast on the air and in the press by charlatans who are actuated only by greed would not find favor with the public if the family doctor gave more specific instructions to his patients than to advise against the ingestion of starchy or greasy foods. Specific instructions in regard to diet necessitate some knowledge of the principles of dietetics. In only forty-two, or 70 per cent, of the sixty medical schools is there any definite attempt at teaching dietetics, and an analysis of the methods of teaching shows that in most schools it is entirely inadequate. In eleven of these schools a dietitian, not a physician, is the sole instructor in this subject. In twelve an internist and in four a biochemist does this work, and in twelve no definite instructor is designated. Ten schools, 17 per cent of the total number answering the questionnaire, designate the gastro-enterologist as the one responsible for the teaching of dietetics. None of the schools give an adequate amount of time to the subject except possibly one, where thirty-six hours of the second year is devoted to dietetics.

It is quite evident that something is wrong about the teaching of gastro-enterology in the medical schools. The statistics obtained after seven years of painstaking work by an eminent commission show that digestive diseases stand third or fourth in the order of frequency of occurrence in a variety of studies. They are an important cause of disability among workers, furnish surgeons with a considerable part of their operative work, and contribute an appreciable amount to the income of undertakers. The preliminary reports of the commission were made available to the medical schools from time to time during the seven years of its work, although they were not published in book form until 1932. Doctors are returning to their medical schools or applying at postgraduate schools, demanding postgraduate instruction in gastro-enterology. The public is turning to quacks and charlatans for its advice in regard to digestive disorders. And what are the medical schools doing about it? It has been shown in the analysis attempted in this study that less than 4 per cent of the time in teaching hours devoted to the teaching of internal medicine is assigned to instruction in diseases of the digestive system and nutrition. An

Study 5 was a study of school children in Hagerstown, Md. by the U. S. Public Health Service, December 1921 to May 1923.

\* From Final Report of the Commission on Medical Education, 1932, upper half of table.

for adequate instruction in their important subject. In six schools clinical teaching is attempted in a short, and often an elective, course in a gastro-enterologic clinic. Inquiry as to the hours devoted to the teaching of gastro-enterology showed three schools giving only an elective course in this subject and twenty-two reporting that no definite number of hours is assigned. Instruction in this subject is given in the junior year in eighteen, or 20 per cent, of these schools, the total number of teaching hours varying from eight to twenty. Thirty-five schools devoted from eight to twenty-two hours to the teaching of gastro-enterology in the senior year. The total number of hours in the entire medical course given to the teaching of disease of the digestive tract averaged twenty-seven hours, which is less than 4 per cent of the time devoted to the teaching of internal medicine in the average medical school. The survey shows no improvement in the situation since the studies of this subject by Simon<sup>1</sup> and by Lucas<sup>2</sup> in 1925 and 1926, respectively. How evident it is that the work of the Commission on Medical Education is being ignored!

1 Simon, S. H., Teaching of Gastro-Enterology in Our Medical Schools, J. A. M. A. 87: 73 (July 10) 1926.  
2 Lucas, C. G., Present Status of Gastro-Enterology in Medical Schools, Tr. Am. Gastro-Enterol. A. 29: 6 1927.

entirely disproportionate amount of time is devoted to subjects of distinctly less importance, such as neurology, psychiatry and dermatology. Even in the preclinical years the digestive system seems to be shunned, only a small proportion of schools giving a course providing an adequate foundation of knowledge on which to build a clinical conception of the diseases of the digestive tract. And correlation between preclinical and clinical instruction is either not attempted or is ephemeral. What is to be done to correct this gross neglect of an important subject? It is evident that an increased number of teaching hours must be devoted to this subject and that the instruction must be planned and carried out by clinicians who have a proper grasp of the needs in this important branch of internal medicine. Gastro-enterology should not be taught as a specialty, as is unfortunately so commonly being done in the case of other medical specialties. The teaching must be integrated with that in internal medicine, in surgery, in roentgenology, in clinical laboratory work, in preventive medicine and even in obstetrics. In the preclinical years adequate time devoted to the anatomy, physiology, chemistry and pathology of the digestive system is not the only need. There must be a correlation between the teaching in these sciences, not only in respect to the need for a preliminary consideration of anatomy, followed by simultaneous instruction in the physiology and chemistry of the digestive functions by these two departments, but by definite attempts at integrating the teaching through combined lectures. These should, of course, precede a consideration of pathology of the digestive organs. During the period devoted to this instruction occasional lectures by clinicians, showing the practical application to the practice of medicine of the knowledge just acquired, will do much to fix in the student's mind the

the time devoted to clinical teaching in a well organized gastro-enterologic clinic should be greater than that given to ward clerkships. It must be realized that a short period of intensive work in one subject, with the ability to follow a few actual patients through a period of diagnosis and treatment, is infinitely more valuable than many scattered hours devoted to many different subjects, and single contacts with a variety of patients.

In regard to the personnel to whom should be entrusted the teaching of this important subject, the

\* Reports to the New York State Board of Health From Report of Commission on Medical Education '1932

report of the commission gives considerable space to the subject of specialism as applied to teaching, and the following extracts from this report seem relevant to this branch of the subject.

"Specialization is necessary in the diagnosis and treatment of some patients and in research, but the educational needs of the student are general in character. Over-teaching in technical fields of science or practice interferes with laying the foundation of learning in the subjects every physician should know. The teaching in the specialties should be integrated with that in general medicine, surgery and obstetrics" (page 200).

"A unified plan of instruction properly carried out should heighten the interest of students in the contributions which the special fields can make to general medicine and surgery" (page 201).

"Emphasis should be laid on the general character of the training to be secured and upon the fact that specialists can make contributions to the training of the student which can not be satisfactorily obtained in any other way. The various specialties have distinct fields in medical practice and to them must be credited much of the advance in knowledge in recent years. No effort to curtail their development or recognition is implied in the suggestion that they should be used only as they contribute to the general training of the student" (page 201).

"Specialists trained in the technique and experienced in dealing with the diseases common in their domain should conduct the teaching in these fields. A study of the work of specialists shows clearly that many of the demands for their services are essentially general in character and that a properly trained physician should be competent to deal with many of the conditions met" (page 202).

These extracts from the commission's report present an admirable and unbiased view of the importance of having specialists do the undergraduate teaching in their fields. The specialist, who is most apt to see the mistakes made by the general practitioner, should realize most acutely what the educational needs of the student must be. It is necessary for him however to concentrate in his teaching particularly on the general phases of his subject, leaving the most technical considerations to postgraduate study. The student must be taught to recognize the more common, easily treated

salient facts in regard to the subject, making it much easier, in the clinical years, to return to a consideration of these fundamental problems. In the clinical years a preliminary didactic or quiz course outlining the principles involved in the diagnosis and treatment of digestive tract diseases preferably given in collaboration, or at least simultaneously, with courses in clinical laboratory and roentgenologic diagnosis should precede the student's actual contact with patients and will save much time in clinical teaching. Realizing that most patients with gastro-intestinal disorders are ambulatory,

diseases in the realm of the specialist and the type of case requiring special study and care. The high mortality from such diseases as acute appendicitis, acute intestinal obstruction and even gastro-intestinal carcinoma can be attributed ordinarily to inadequate instruction in the medical schools, and the awe with which the average general practitioner contemplates a diagnosis of such common and relatively simple diseases as peptic ulcer and gallbladder disease may be similarly attributed to a lack of familiarity with those conditions which should be acquired during his medical course.

In an effort to suggest an improvement in the teaching of gastro-enterology in medical schools I present with all diffidence, and with a realization of its shortcomings, the following outline of a comprehensive course covering the disorders of digestion through the average four year course in medicine. The instruction should be planned and carried out by trained gastro-enterologists functioning as a separate department.

#### A PLAN FOR THE TEACHING OF GASTRO-ENTEROLOGY

##### *First and Second Years*

**Anatomy.** Instead of isolated studies of the various parts of the digestive tract, a definite course should be given in the anatomy and histology of the tract as a whole from mouth to anus, demonstrating the accessory organs, the relations to other organs and the innervation of the tract. This course could be greatly aided by a roentgen study of the barium filled gastro-intestinal tract preceding dissection of this tract.

**Biochemistry.** The chemistry of digestion and nutrition should be taught in a way to emphasize its importance from the clinical standpoint and the course should immediately precede the consideration of the functions of the digestive tract by the department of physiology.

**Physiology.** The study of secretion, digestion and nutrition should supplement and amplify the information obtained in the course in biochemistry. The neurologic control of the digestive functions should be studied in an orderly way. The motility of the gastro-intestinal tract can best be taught in an efficient and graphic way by means of fluoroscopic observations by small groups of students, of one of their number who will volunteer to take a barium meal.

The bacteriology and pathology courses have as a rule been quite adequate. Pathologic conferences in later years, in conjunction with the department of internal medicine, help to crystallize the knowledge previously obtained.

**Pharmacology and Materia Medica.** A short time given to the effects of drugs on the functions of the gastro-intestinal tract would do much to dispel the many misconceptions in regard to this subject.

During these courses of the first and second years an experienced gastro-enterologist should give an occasional clinical lecture or demonstration illustrating the practical application of what the student has just learned to the practice of medicine. This will help to fix the subject in the student's mind and will simplify later instruction in clinical medicine. At least two or three such lectures should be given each year.

##### *Third and Fourth Years*

**Lecture Course.** A preliminary course of at least twelve lectures covering the general principles involved in gastro-enterologic diagnosis and treatment and a brief consideration of the principal, common, diseases of the digestive tract should precede the clinical courses.

The course in clinical laboratory procedures should include a practical consideration of gastric analysis, examination of duodenal contents and stool examinations.

There should be, if possible, a period of at least six or eight weeks during which the students in small groups attend regularly a thoroughly organized gastro-enterologic clinic where they can become trained in careful history taking and physical examination and can observe and assist at the clinical laboratory tests, roentgenologic studies and therapeutic procedures.

In the hospital clinical clerkships, care must be taken that each student gets a fair proportion of gastro-enterologic cases. Conferences between the small groups of students and the attending gastro-enterologist who is in charge of the patients to whom the students have been assigned should consist of the reading of history and physical and laboratory observations by the student, a review of the literature on the subject of the patient's disease which the student has looked up in the library, a demonstration of x-ray films of the patient and of similar cases, a discussion of the possibilities in diagnosis, and an outline of the treatment and operative indications. Where possible, specimens from the pathologic museum should be used to illustrate the character of the lesion. The student in his record of the case, should make continuation notes, and he should be given time to follow his patient into the fluoroscopic room, the examining rooms of other special departments, and, in operative cases, into the operating room. Preoperative and postoperative care must be taught by actual demonstrations on patients.

Dietetics, the biologic principles of which have been taught in the early biochemistry course, should be discussed in detail by the gastro-enterologists and internists in the course of their clinical teaching, should be covered in principle in a few special lectures by these instructors, and should receive practical consideration in a brief course in the diet kitchen, where the preparation of foods and their arrangement into suitable diets can best be demonstrated. Bedside observation of the diets of patients at meal hours is also a valuable aid in teaching.

Gastro-enterologic roentgen diagnosis, begun in preclinical years when the study of normal anatomy and physiology was clarified by film and fluoroscopic studies of the gastro-intestinal tract should be taught to small sections of students by means of observations in the fluoroscopic room, guided by a competent roentgenologist and preferably also by a gastro-enterologist and by a demonstration of groups of films by the roentgenologist. This work will supplement the demonstration of films of actual patients under the student's observation in the clinic or the hospital ward.

During the clinical years an occasional amphitheater clinic which the whole class can attend, given by the head of the gastro-enterologic department or by a visiting gastro-enterologist, will help to stimulate interest in gastro-enterologic problems. Lectures or clinics held in conjunction with the departments of surgery, obstetrics and pediatrics will help to emphasize the importance of a broad outlook in the consideration of gastro-intestinal symptoms.

#### COMMENT

The course in gastro-enterology outlined, while at first glance appearing to be too complicated and lengthy for practical consideration, can really be covered in a surprisingly small number of hours. It must be remembered that this should not be in the nature of an intensive postgraduate course, but its aim should be to acquaint the student with the symptoms of the most common gastro-intestinal diseases, the methods of study and the principles underlying treatment. A constant reference to the physiologic principles involved helps to fix the subject in the student's memory and makes it easier for him to work out his own cases. The preclinical work will involve no extra expenditure of time but merely a rearrangement of present schedules. The time devoted to gastro-enterology in the clinical years should consist of from twelve to fifteen hours of preliminary lectures and from four to eight hours of later clinical lectures to the entire class. The minimum number of hours spent in the gastro-enterologic clinic should be from twelve to fifteen. The exact time devoted to ward assignments cannot be accurately estimated, but the small group conferences should embrace at least twelve to sixteen hours, and the dietetic and roentgenologic conferences should take another six to twelve hours. Our plan, therefore, for a unified study of gastro-enterologic problems involves

the assignment of at least forty-six hours to this subject, which is still considerably less than 10 per cent of the time devoted to internal medicine in some schools and less than 5 per cent in many. The importance of the subject would surely warrant the expenditure of at least 15 or 20 per cent of the time, and it is to be hoped that the day will come when the average medical school will devote at least 100 hours to the teaching of gastro-enterology.

#### SUMMARY

1 The importance of gastro-enterology as a teaching problem has been demonstrated by the Final Report of the Commission on Medical Education in its conclusions in regard to the prevalence of digestive diseases in general practice.

2 The medical schools of the country have not yet become cognizant of its importance, and the teaching of this important subject is woefully neglected in all but a few of the schools.

3 The commission has called attention to the value of having the specialist do the teaching in his special subject, and this applies with special force to the teaching of gastro-enterology.

4 An adequate course in gastro-enterology should include a correlation between preclinical and clinical teaching and integration with the courses in internal medicine, surgery, obstetrics and other specialties.

5 A plan for the teaching of gastro-enterology is presented, which involves a minimum of forty-six hours devoted to this subject and a recommendation for a larger number of hours wherever this is feasible.

88 Sixth Avenue.

## POSTGRADUATE DERMATOLOGIC TRAINING

### ITS RELATIONSHIP TO CERTIFICATION OF SPECIALISTS IN DERMATOLOGY

#### CHAIRMAN'S ADDRESS

C GUY LANE, M.D.  
BOSTON

The supervision of specialism with emphasis on certain educational aspects was discussed in detail before the American Dermatological Association last year by Dr. Fred Wise in his presidential address. Since that time there has developed a certain amount of misunderstanding concerning the objects and work of the American Board of Dermatology and Syphilology, so that it seems worth while to review some phases of the board's activities and particularly its relationship to postgraduate training in dermatology and syphilology.

#### OBJECTS

The board has been established with the object of improving standards of practice in dermatology and syphilology. In furthering this aim it is necessary to determine the competence of physicians who specialize in dermatology and syphilology. This entails the determination of adequate standards of fitness, the conducting of investigations and examinations to test the qualifications of voluntary applicants, and the granting of certificates to those applicants who successfully fulfil the established requirements. For the benefit of hospitals, medical schools, other physicians and the lay public the board will make available lists of those

physicians who have been certified by the board. Other boards which antedate ours have found that in order to accomplish their purposes it has been necessary to study and attempt to improve the facilities which provide instruction in their particular fields, and it is one of the objects of this board to survey the postgraduate facilities for training in dermatology and syphilology. It is expected, as a result of the work of this board that better undergraduate and postgraduate training facilities, both clinical and laboratory, will be furnished that better dermatologists will be provided as a result of this training, and that as an ultimate result greater progress in the scientific attack on skin disease will be made and better service will be rendered in dermatology and syphilology by both the specialist and the general practitioner.

#### ACCOMPLISHMENTS

In the year and a half since its actual formation, the board has become incorporated and developed its program. It has investigated the methods used by the other boards and it has developed methods of procedure on the basis of experience of these boards. It has also considered thoroughly standards to be expected of individuals in practice for a varying length of time. It has received 221 applications and has held three meetings. At two of these meetings the board has examined forty-nine applicants. More than 190 certificates have been issued. A list of those certified by the board has already been published, and further lists will be issued from time to time.

The board has also initiated an educational survey based on certain standards of postgraduate training in dermatology and syphilology which are acceptable to it. Briefly, this standard at present provides for at least two years of well planned intensive training in the clinical, laboratory and therapeutic branches of dermatology and syphilology. Approved postgraduate training should include (1) adequate clinical and laboratory facilities, (2) properly supervised instruction under a staff of approved dermatologists, (3) opportunities for properly supervised research work, and (4) access to adequate dermatologic literature.

Among its other accomplishments may be mentioned participation of this board in the formation of the Advisory Board of Medical Specialties, which plans to coordinate the work of the various specialty boards and those organizations interested in medical education especially postgraduate education. These accomplishments indicate to a slight degree the importance of the work to be performed by the board. Of additional significance is the fact that the American Dermatological Association has already voted to require a certificate of all new members admitted after 1935. A representative of the American Hospital Association stated last winter that an attempt has been started toward the adoption of a similar resolution for staff appointments in the various hospitals belonging to this association. It seems probable that medical school faculties may adopt a similar requirement.

#### SOME MISUNDERSTANDINGS

One of the points on which confusion has arisen is in regard to the use of the word "license." The term license implies governmental or municipal restrictions, or some legal qualifications but no license to practice dermatology or syphilology is even considered by the board, as it has nothing whatever to do with the licensure of specialists. In the second place, there has been some confusion concerning the American Board of

Dermatology and Syphilology and the American Dermatological Association. The board is related to the latter association only as it is related to the Section on Dermatology and Syphilology of the American Medical Association. The board was formed as a result of the reports of committees appointed by both of these organizations, and each of them contains equal repre-

TABLE 1—Age Groupings of Diplomates

70 plus years	1
Total	139

sentation on the board. Thirdly, no one is compelled to apply for a certificate issued by the board. The establishment of the board affords an opportunity for physicians desiring to become accredited specialists to make application voluntarily, present credentials, take examinations (if such are deemed necessary), and receive a certificate (if their credentials and examination are satisfactory) as a diplomate of the American Board of Dermatology and Syphilology. Fourthly, a physician obtaining this certificate does not become a member of the board. The members are the representatives designated by the two component societies. The term "diplomate" is applied to a physician who fulfils the requirements of the board and receives a certificate. The work of our board in the field of dermatology and syphilology parallels the work of the National Board of Medical Examiners in the field of general medicine. The formation of national specialty boards will obviate the confusion that might arise from the establishment of a number of state licensing boards for specialists, a plan that has previously been proposed. I do not mean that it will be possible to prevent eventually the licensing of specialists in this country as it is done in other countries, but the work of the board should go a long way in determining physicians properly prepared for admission to the practice of this specialty.

#### RELATIONSHIP TO POSTGRADUATE DERMATOLOGIC EDUCATION

With this statement of the board's activities I turn to its relationship to postgraduate dermatologic education. In this connection it has seemed advisable to ascertain the type of postgraduate training received by the diplomates of this board up to January 1 of the present year. The application blanks of these 139 diplomates are only a small number on which to make generalizations, but I feel that a study furnishes sufficient information to aid as a guide for a short period in a project on which today little information exists.

A study of these application blanks shows that the oldest is 72 and the youngest 30 years old. The age grouping is given in table 1.

It was also noted that fifteen of these applicants have been graduated from medical schools outside the United States and that ninety, or 65 per cent, had had some general practice, varying from one to twenty-five years. The great majority of these (88 per cent) had held internships in hospitals previous to their specialized training. One hundred and one diplomates are teaching dermatology and syphilology in class A medical schools, fifteen have held such positions, and only twenty-one, or 15 per cent, have had no teaching experience.

It has been difficult to develop data in regard to the length of training in this group. In many cases the exact month and year have not been stated, and the period of training has overlapped the beginning of private practice. In addition, many men obtained their training on a part time basis and it is difficult to compare such training with that received as full time assistant or resident. Table 2 shows the best approximation it was possible to make from the study of these applications.

For the purpose of studying the postgraduate training, the application blanks have been reviewed on the basis of years of limitation of practice to dermatology and syphilology (table 3).

There are certain facts about each of these groups of various lengths of practice which it is of interest to detail briefly. Of the three individuals in group I, two spent from one and one-half to two years in postgraduate work abroad, and two of them spent further time as assistants on their return home.

Of the three who have practiced from thirty-five to thirty-nine years, two (or 60 per cent) spent from one and one-half to two years abroad in work, and two were assistants to well known dermatologists for a period of years.

Nine have practiced from thirty to thirty-four years. Seventy-five per cent studied abroad from eight months to almost three years. Six of these individuals had been in general practice for from one to eleven years before going into the specialty.

Of those practicing from twenty-five to twenty-nine years there were fourteen, and twelve (or 85 per cent) of these spent from seven months to two years abroad. In this group eight were recruited from the ranks of general practitioners. At the same time it is worth noticing that four of these individuals had held special internships for skin diseases.

In group V, sixteen in number, only one half took their training abroad and a larger percentage, twelve, had previous experience as general practitioners. The average time spent abroad in this group was distinctly shorter than in any of the former groups.

Of the fifteen to nineteen year group of twenty six physicians, only seven spent any time abroad. It is to be remembered that this group began their training during the war and the facilities for postgraduate training at that time were greatly disrupted. Five of these men held residencies or internships and twenty one had had general practice for from two to nineteen years before entering dermatology.

TABLE 2—Length of Training

Training Period	Number
4 years or more	24
3 to 4 years	18
2 to 3 years	41
1 to 2 years	29
6 to 12 months	19
Uncertain	7
Total	133

The largest group of all is the ten to fourteen year group of forty-two physicians. Only six of these individuals had any training abroad and that training in general was for short periods. In this group two other tendencies are noticeable. About 25 per cent of the men took internships or residencies as the major part of their training. About half the men, twenty-two in all, received their training as assistants to well

known dermatologists, together with experience in clinics which their chiefs controlled. There was a falling off in the percentage that entered from private practice, only twenty-eight having had previous general practice experience. There were also a number who signified their taking of short postgraduate courses as a part of their training.

TABLE 3—Limitation of Practice

Group	I	40 to 45 years of practice	3
	II	35 to 39 years of practice	3
	III	30 to 34 years of practice	9
	IV	25 to 29 years of practice	14
	V	20 to 24 years of practice	16
	VI	15 to 19 years of practice	27
			72
	VII	10 to 14 years of practice	42
	VIII	5 to 9 years of practice	25
			67
Total			139

In the youngest group, those in dermatologic practice for from five to nine years, there were twenty-five men, and of these six men received their training abroad, and several of them for relatively long periods. The limits were from six months to four years. A still larger number, sixteen, or 64 per cent, received their training as assistants in the offices of well known men. Seven held residencies or internships. Fourteen of these men, or 56 per cent, had had previous experience as general practitioners. Five of the men in this group have received their training in institutions conferring a degree of Master of Science in Dermatology or Doctor of Medical Science. This is another new development in the training methods for dermatologic practice. About half, or seventy-two, of these diplomates have limited their practice for fifteen years or more, and sixty-seven have limited their practice for from five to fourteen years.

SOURCE OF TRAINING

In reviewing these applications and the training that was received for specialization in dermatology and syphilology it is apparent that these methods of training can be divided roughly into five groups (table 4). There is, of course, much overlapping, and certain individuals will perhaps have received training in several of these different groups, but in general such a grouping can be clearly made out.

First, there is the group of those physicians who have studied outside the United States. Fifty-one diplomates, or 36.6 per cent, received some training in other countries. This training has usually been taken early in their dermatologic career, but eleven of the men went abroad later for short courses of training, usually of a few months' duration. Twenty-nine received the major portion of their dermatologic training abroad, the majority of them for more than a year. Eighteen were abroad for from four to twelve months, and twenty-one for more than a year. Some of these became assistants to well known dermatologists on their return, and a few entered a residency or internship in addition to an assistantship. I have already called attention to the smaller percentage of men going abroad since the war.

In the second group are fifty-six diplomates, or 40 per cent, comprising those physicians who have received their training for the most part as assistants to well known dermatologists, usually for a period of from one to five years. At the same time they have had training in the clinics of their chiefs. The number of younger men in this group, thirty-three, with less than fifteen

years of limitation of practice, indicates a distinct tendency on the part of the younger specialist to obtain his training in this country in direct relationship to some one of the older and more experienced men. Ten of these men also had short courses of graduate training abroad for usually less than one year's duration. Twelve diplomates had held a residency before the assistantship.

The third group, twenty-six in number, or 19 per cent, includes those physicians who have served for a definite time in a hospital with beds for the care of skin and syphilis patients and have there received a specialized training in this field. These positions have been spoken of variously as internships, residencies or fellowships. The duration of this service has ranged from six months to three years. Many of these individuals on the completion of their residency or internship have become assistants to well known dermatologists. There are also a few who have taken work abroad after the completion of their residency for a period averaging from six to eight months. The 1931 Directory of the American Medical Association contains a list of twelve hospitals in which residencies for dermatology are maintained. Not all of these, however, can be relied on for adequate training, and the list omits certain institutions where even better training can be obtained under the title of Fellows. The training which this group has received has been for the most part obtained at the Skin and Cancer Hospital in New York, the Mayo Clinic, the University Hospital at Ann Arbor, the City Hospital and Lakeside Hospital in Cleveland, the Barnard Skin and Cancer Hospital at St. Louis, and the Massachusetts General Hospital in Boston.

The fourth group includes only five men, but their training is a definitely forward step in postgraduate teaching. These men have obtained a Master of Science in Dermatology or a similar degree from the postgraduate department of a medical school on the completion of from two to three years of study. This period has included rather strict supervision of clinical and laboratory activities, together with the satisfactory

TABLE 4—Source of Training

	Total	Practice Limit 15-45 Years 72	Practice Limit 5-14 Years 67
Abroad	51	39 18 (4 to 12 mos) 21 (1 year plus) 9 (later)	12 4 (2 to 12 mos) 4 (3 yrs plus)
Assistantships	56	23 (17 yrs) In addition 6 studied abroad 5 held residencies	33 (9 mos to 5 yrs) (3 below 1 yr) In addition 7 held residencies 2 studied abroad
Residencies and fellowships	26	12 (13 yrs) In addition 3 studied abroad 4 held assistantships	14 (13 yrs) In addition 6 held assistantships
Master of science	5	0	5
Clinical experience	55	18	17

completion of a regularly outlined program and the acceptance of satisfactory research work. This degree is at the present time awarded by only five institutions, namely, University of Pennsylvania, University of Michigan, University of Minnesota, Columbia University and Northwestern University. The University of Illinois also issues an M. A. on the satisfactory completion of one year's work.

applications that do not fit into any of these four are thirty-five in number, about 25 per cent applications show that practically all these men received most of their training by clinical experience in and syphilis clinics, often supplemented by short courses in large centers. The older and younger groups equally considered are represented equally among applications. Only three of these men have had training abroad. Twenty-four of these men, or two thirds, had, in addition to their clinical experience, courses of postgraduate training in larger hospitals. Five of them have taken courses of less than six months' duration, the rest of them signifying varying periods of training up to two years. It was also found that twenty-four who have taken courses that the older and younger groups were again equally divided. There were ten diplomates who had received their training from clinical experience alone, with an equal number in both the older and younger groups. A few of them have also held assistantships for short periods. It is interesting to note that twenty-five of this whole group are at the present time teaching in class A medical schools, the great majority of them with a professional rank.

## COMMENT

In the first place, as one reviews these data, one is impressed with the high percentage of specialists who received their training abroad twenty-five years ago or earlier.

Following this came a very complete falling off in postgraduate training abroad during and shortly after the war, with a return in the last ten years to postgraduate study abroad, 25 per cent of the younger men availing of such facilities and in this time remaining abroad for longer periods than before.

In the second place is to be noted in the last fifteen years the development of postgraduate training as assistance to well known men in our field.

Thirdly, there is a rise in the internship or residency fellowship as a factor in postgraduate teaching due to the greatly increased facilities made available in this country and the tendency toward specialization.

Fourthly, has come perhaps the most striking development, the awarding of a postgraduate degree, Master of Science in Dermatology. This recognition of a satisfactory period of training, perhaps in connection with a fellowship, will become more general, I believe, as postgraduate medical education expands and improves under the guidance of class A medical schools. It is hoped that funds will become available as time goes on so that more physicians of high caliber interested in a specialty and deserving of such training need not depend on clinical experience alone.

One notes also that 25 per cent of these applicants obtained their training in dermatology on the basis of clinical experience, usually supplemented by courses in some larger institution. Two thirds of these men received a teaching position in dermatology in a class A institution, the great majority with a professional rank. Financial reasons are undoubtedly the main factor in determining this choice of training. Long clinical experience may provide sufficient training for practice in a specialty but it does not provide the knowledge of fundamentals needed for well rounded practice in a special field. If postgraduate work also is taken, and trips to large clinics for short periods made at intervals, such men may keep abreast of progress in a specialty. At the same time such a man is always more or less handicapped by a relatively

incomplete start, and it is probable that some one of the other four methods described will furnish a distinctly better fundamental training. It is not possible to say at the present time which of these methods is the best. A great deal, of course, depends on the characteristics of an individual as it does in any profession or business, and the fact that so many men have attained teaching positions in the last group, I believe, points fully as much toward the individual as a factor as to the training that he received. In other words, these individuals would probably have been better specialists if they could have had one of the types of training cited. It would seem better therefore, to insist on better standards of fundamental training in order to furnish better trained men for the practice of a specialty.

As a part of the endeavor to accomplish this purpose, the Advisory Board of Medical Specialties has created the Committee on Standards and Examinations. Among other matters this committee has inquired into the standards of the various specialty boards, has considered the matter of postgraduate training, and is placing before the advisory board at its meeting here in Cleveland a report on the minimum requirements for admission to the examination of a medical specialty board, as follows:

Each applicant should have certain (a) general qualifications, (b) professional education, (c) specialized training.

## A. General qualifications

- 1 Satisfactory moral and ethical standing in the profession
- 2 A license to practice medicine
- 3 Membership in the American Medical Association or, by courtesy, membership in such Canadian medical societies as are approved by the Council on Medical Education and Hospitals of the American Medical Association

## B. Professional Education

- 1 Graduation from a medical school of the United States and Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association

- 2 Completion of an internship of not less than one year in a hospital approved by the same council

## C. Specialized Training, to be effective as far as practical not later than Jan 1, 1938

- 1 A period of study after the internship of not less than three years in clinics, dispensaries, hospitals and laboratories recognized by the same council as competent to provide a satisfactory training in the special field of study

- 2 This period of specialized preparation should include
  - (a) intensive graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment of conditions in that particular field,

- (b) an active experience of not less than eighteen months in hospitals, clinics, dispensaries and diagnostic laboratories recognized by the council as competent in the specialty,

- (c) examinations in the basic medical sciences of a specialty as well as in its clinical laboratory and public health aspects

- 3 An additional period of not less than two years of practice. In case of an applicant whose medical training has been received outside of the United States and Canada the credentials must be satisfactory to the Advisory Board.

## TRENDS

The trend in modern medicine has been toward specialization, and with this trend many men have entered a specialty with inadequate fundamental training, often realizing this deficiency too late to make up for it adequately as they have become increasingly busy with their practice and hospital work. From an examination of these records there is a definite trend toward postgraduate special training in this country, either as an assistant to a well known specialist or as a resident

or fellow or in a prescribed two or three year graduate course in dermatology provided in several institutions. There is also the trend toward obtaining a postgraduate degree in dermatology. Furthermore, in the formation of the various boards there is a very definite trend toward the control or regulation of specialists. There is some feeling among authorities studying medical education that the licensing of specialists will be ultimately reached. There is no doubt of the fact that more stringent qualifications for the practice of a specialty will be required and that candidates for teaching positions and hospital staff appointments will be selected from those individuals fulfilling these higher requirements.

#### CONCLUSION

I have attempted to clarify any misunderstanding about the activities of the American Board of Dermatology and Syphilology. I have also reviewed the preparation for special practice which the diplomates of this board have received, indicating some of the significant changes that have occurred and the trends suggested by this study. We as physicians and as specialists in dermatology and syphilology must accept the fact that these changes are in progress at the present time and furthermore that we must participate actively in this adjustment period. We should review the situation thoroughly and lend our aid, as individuals as well as an organization, in the program to regulate or control our specialty, perhaps best through the board that has been formed for this purpose rather than at some later period undergo the restrictions imposed on us by governmental or other outside agencies.

416 Marlborough Street

### THE RELATION OF POSTGRADUATE MEDICAL INSTRUCTION TO PUBLIC HEALTH

LEROY E. PARKINS, M.D.

Secretary to the Harvard Medical School Courses for Graduates  
BOSTON

Public health service originated in the minds of doctors who recognized the need of the community for this important branch of medicine. Jenner and Waterhouse were practitioners of medicine as well as the founders of preventive medicine and the forerunners of modern public health service. Oliver Wendell Holmes was likewise an ardent champion of preventive medicine as well as a practitioner of the medical art. Austin Flint, the eminent physician and cardiologist, was one of the earliest epidemiologists; he conclusively established the source of an epidemic of typhoid in New York State when there was error and much confusion of thought in regard to the etiology.

The practitioner of medicine by tradition is interested in public health problems. His enthusiasm for and cooperation in public health programs has varied from time to time. By training, the physician is taught to individualize his knowledge to a great degree. However, it is known that often a single patient's disease may have a direct bearing on community health. Thus the early, accurate diagnosis and treatment of an individual's contagious disease is the best kind of preventive medicine for the community. This type of case

treatment is a public health problem and is recognized as such by the public and profession in a large group of contagious diseases.

Hard and fast lines cannot be drawn between public health problems and the private practice of medicine. These two types of medical work have the common aim and purpose of maintaining the highest degree of community health. The public health physician attacks this problem primarily from the group standpoint, while the private physician is concerned chiefly with the individual patient. The public health physician has a large field of undisputed practice in guaranteeing pure food and water supplies, supervision of quarantine laws, and all similar public safeguards. These are obvious mass health problems. The improvement of community health beyond these broad realms is largely a problem of individual attack. If this is true, the situation cannot be adequately met in the most efficient manner unless the best remedial and preventive medical service is available to every person. This is possible only through the united efforts of public health physicians, private practitioners and their co-workers. No corps of public health physicians and nurses can alone hope to cope successfully with this immense, vital, human problem without the friendly, active cooperation and assistance of the whole medical profession. That this cooperation has not existed at all times is patent to any observer who reads vital statistics for various communities. There have been occasions when health departments have attempted to provide facilities for postgraduate instruction without great success. The causes of such failures are varied; they are usually due to lack of mutual understanding and full appreciation of the fact that all physicians have many common interests and problems irrespective of their fields of work. However, it is not an idle dream to hope for better results from real cooperation between these two groups of the medical profession.

New discoveries and improvements are constantly being made in all fields of medicine and related science. It is a major problem in private practice as well as in the realm of public health to provide the practicing physician and health worker with this new knowledge, which may be of the greatest importance to individual and community health. A working educational system is needed that is flexible enough to meet all practical requirements. There are two modes of direct approach to the problem of postgraduate medical instruction: one is for doctors to return to postgraduate medical centers for study, the other is to take postgraduate courses to the individual communities. For the best results both of these methods should be used in much larger measure than is done at present. There has long been much indirect teaching through medical books and journals, but this is not sufficient to meet present day needs. In addition, direct methods of personal teaching are desirable and practicable.

It is interesting to know about some successful cooperative efforts in postgraduate medical instruction which have been carried out to the mutual advantage of the public and the profession. The Detroit Department of Health has inaugurated a program of postgraduate instruction in cooperation with the Wayne County Medical Society. This instruction aims to develop interest and proficiency in the practice of preventive medicine by the practicing physician. This health department started a program of weekly clinics in 1930. The first year the largest attendance was

forty-five, while in the last season as many as 300 physicians were in attendance at one session. The teaching material has been enlarged to include many problems related to the diagnosis, treatment and prevention of the acute communicable diseases.<sup>1</sup> Also the state health departments of Georgia, Massachusetts, North Carolina, Virginia and other states have cooperated with the state medical societies in giving postgraduate extension courses.

The following data on the successful cooperation of the Massachusetts State Health Department with the Massachusetts Medical Society in inaugurating a state-

The background of more than 4,000,000 people who need and expect good medical service provides a strong incentive in motivating this work. The Massachusetts Medical Society is the central professional group which is interrelated with all the organizations named in the upper section of the chart, the component district societies are named in the lower section.

Chart 2 explains how the Massachusetts Plan of Postgraduate Medical Instruction functions. The committee on postgraduate instruction is a group of eighteen doctors. Among the members are representatives of all sections of the state society, the chairmen of the standing committees of the medical education and diplomas and public health, the editor of the *New England Journal of Medicine*, the state health commissioner, the state commissioner of mental diseases, the deans of Boston University, Tufts and Harvard medical schools, or their official representative, and the president of the Boston Medical Library. This committee formulates plans and policies, the work of organization and administration is delegated to an executive committee of three, an executive secretary is also a member of the committee. In actual operation this past year the executive committee arranged a curriculum and provided a faculty, which was drawn largely from the medical schools. However, some non-medical school faculty instructors gave splendid service. The committee has a free hand to secure teachers from any source. When this program was started, the Harvard Medical School abandoned all its work in giving postgraduate extension courses in Massachusetts. It is the opinion of the Massachusetts Medical Society that it is the duty of the organized profession to carry on this type of graduate instruction. The committee has received active assistance from the state health department, the state department of mental diseases, many community and private general hospitals, and the medical schools. As this work develops, other related organizations will be of assistance.

The Massachusetts Medical Society program of postgraduate instruction was finished on May 15, 1934. The total benefit to the profession and the public is difficult to evaluate, however, this value may be estimated from the fact that 1,002 doctors enrolled in twenty-two courses, which were given in groups of ten subjects in twenty-four different cities. A faculty of 170 instructors gave the course of study. The cost per member was \$5 for registration, and the project is essentially self supporting. The Massachusetts Medical Society plans to continue this work. The success of the Massachusetts Plan has been due to the splendid cooperation of the state health department, the medical schools and other professional groups who have worked with the state medical society.

Is it not reasonable and desirable that public health physicians should take a more active interest in programs of postgraduate medical instruction? Specialists in public health are in an advantageous position to assist practicing physicians to provide better medical service. The best medical care for the individual and community is possible only by having highly trained and efficient physicians who carry on their work enthusiastically. There has been much criticism of the present social order of medical service. Is it not a possibility that much of the difficulty is the inadequate and uneven distribution of the knowledge of how to provide the highest grade of modern medical service? The actual need of society is not essentially cheap medical service,

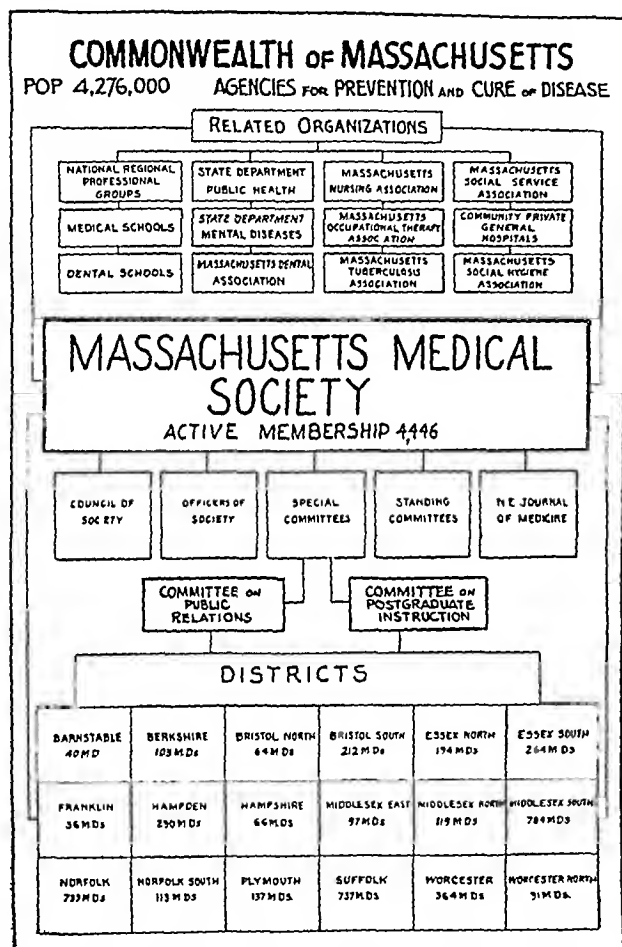

Chart 1—Relation of the department of postgraduate instruction to the state society as a whole

wide program of postgraduate medical instruction may be of interest in visualizing ways and means of active participation by public health physicians in assisting the organized profession to secure instruction in preventive and curative medicine. This experience is not of great length, but it has been successful. The Massachusetts Medical Society has just finished its first year of state-wide postgraduate extension instruction which has functioned in 100 per cent of the state. Every district society has taken an interest and proved that doctors everywhere, whether they reside in city or village, have a genuine interest in improving their ability.

Chart 1 shows the relation of the department of postgraduate instruction to the state society as a whole. This work is carried on under a special committee

<sup>1</sup> Gordon J. E. medical director health department of the city of Detroit. Personal communication to the author.

rather the need is for the highest grade of medical care. As in most other realms of the social order, the best is usually the cheapest in the long run. No plan of mass medical service by insurance schemes, state medicine or otherwise will rise higher than the average working intelligence of the physicians who give such service. Would it not be to the mutual benefit of the profession and society if much more effort were spent in providing facilities for adequate postgraduate medical instruction? There is a great awakening of interest among the profession in postgraduate study. The history of the profession is one of constant progress. I believe that the

personal contact through medical coordinators, and finally, perhaps most important, by adequate undergraduate instruction. The work to which I refer deals with the first of these activities. For a number of years an attempt was made to interest physicians in programs of preventive medicine through circulars, by distribution of printed instructions and by talks before medical societies. The conclusion was reached that a more fruitful line of attack would be actual demonstration. There is often in public health education too much of lectures and literature and not enough of actual demonstration of method. Weekly clinics were organized, to which all physicians of the city were invited. Patients were presented, there was illustration of the methods of early diagnosis, and actual demonstration was made of the technic of specific preventive measures and of tests for immunity. Attendance at these clinics progressively increased. This suggested that the method met a need and stimulated the interest of physicians.

DR E. R. HAYHURST, Columbus, Ohio: May I ask the plan of financing? Whence comes the money?

DR BENJAMIN GOLDBERG, Chicago: This type of instruction has been of interest to those engaged in tuberculosis work because of the difficulties encountered by the general practitioner in making a diagnosis of early tuberculosis. In Chicago in 1927 I instituted a plan of tuberculosis education based on the development of a temporary school in a community, to which medical practitioners might come without much loss of time. The local medical society branch furnished a group of physicians interested. The material for teaching was taken to an available hall or auditorium in the vicinity. Lectures were given by specialists in various fields—bacteriology, pathology, physical diagnosis, roentgen diagnosis and childhood tuberculosis. Following the didactic work, practical demonstrations and examination of patients by the practitioners' student group were given in adjacent tuberculosis dispensaries until capability was demonstrated in the recognition of pulmonary disease.

DR LEROY E. PARKINS, Boston: In Massachusetts the state medical society appropriated \$1,000 the first year to defray the beginning expense, but it was also voted to charge \$5 for each member who registered for the course. Actually the \$1,000 appropriated was never used. The \$5 registration fee amply covered all expenses. The state society organized a faculty of 170 instructors. We really organized a postgraduate school within the medical society. The best instructors available in Massachusetts gave the courses. Some of them were private practitioners from various parts of the state. The committee was given a free hand to obtain instructors from any source. The first year it was agreed to pay no salary to instructors beyond the actual expenses. We were liberal in allowing any expenses they wanted to incur. At the present we are just finishing the first year, so that we have not made a final accounting, but I know we are going to come out with a balance to the good. Just now we are organizing the curriculum for next year. Twenty-two individual subjects were offered last year, that will be reduced this year to probably ten groups, actually thirty subjects. Each district society will be allowed to choose three groups and one elective. We are very liberal in our agreement to give any type of instruction. This has included tuberculosis, gonorrhea, syphilis, pneumonia, fractures, surgery, obstetrics and the general run of medical subjects. We are fortunate in having the state 100 per cent organized. We have an excellent chairman in each district, who has been wonderfully cooperative with the state committee in each case, so we have had splendid service from them. They are organized as a committee, last week they met in Worcester at the state convention, and told us what they wanted, now it is our job to provide what they want. This project of giving instruction to the medical profession is one of the greatest things the organized medical society can do, and I am certain that it can be financed in any state. Canada does it on a national scale, the Sun Life Insurance Company has given \$30,000 a year to the Medical Association of Canada for six years to carry on extension teaching. If there is any one here from Virginia, I think he could tell you about the Commonwealth Fund, which gave the Medical Society of Virginia \$10,000 to help organize the work there.

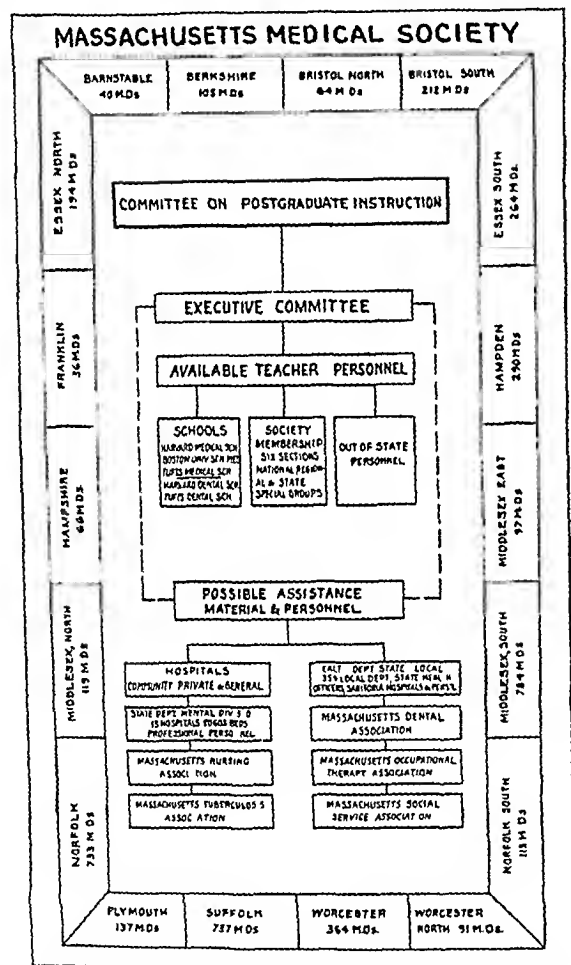

Chart 2—Diagram of how the Massachusetts Plan of Postgraduate Medical Instruction functions

present medical personnel can meet present day problems. Opportunities for continued study and inspired leadership are the profession's greatest needs.

#### ABSTRACT OF DISCUSSION

DR J. E. GORDON, Detroit: In 1930 a scheme of postgraduate instruction was started in Detroit, relating particularly to problems in the control of communicable diseases. Preventive medicine profits in proportion to the increased interest and activity of the private physician. Vaughan has emphasized that successful participation of the private physician in preventive medicine depends on three factors: the prepared physician, the prepared public and a sympathetic health agency. An increased interest of the physician in the possibilities of preventive medicine as contrasted with curative medicine, together with instruction in the technic of the methods involved, has been attempted in three ways—by postgraduate instruction, by

## CONSERVATIVE TREATMENT OF LATE TOXEMIAS OF PREGNANCY

WITH SPECIAL REFERENCE TO THE INTRAVENOUS USE OF MAGNESIUM SULPHATE

LYLE G. McNEILE, MD  
LOS ANGELES

F. S. Newell,<sup>1</sup> in addressing the alumni of the New York Lying-In Hospital, Nov. 12, 1913, said "Any one reading the two papers on eclampsia which were presented at the last meeting of the New York State Medical Society, one on the surgical and one on the medical treatment of eclampsia unless he has strong views of his own, would be in serious doubt as to how to treat a case of toxemia because he is told on the one hand that the only real hope of the eclamptic patient lies in the immediate emptying of the uterus

and on the other hand he is assured that the only safe method of treating eclampsia is by purely medical means." Twenty years later, the routine surgical treatment of eclampsia cannot be seriously considered by one who has even superficially examined the contributions of Stroganoff<sup>2</sup> and others. The definitely lowered maternal and infant morbidity and mortality in clinics employing conservative methods is well established.

The treatment of a disease of unknown etiology must of necessity be empirical, and this is particularly true of eclampsia. Theories and opinions advanced by investigators of unquestionable honesty and technical ability have been at such variance that the average practitioner is often confused in regard to the specific details of any one of the standardized procedures and the results which may reasonably be expected from such procedures.

My purpose in this presentation is to supplement a report<sup>3</sup> on the intravenous use of magnesium sulphate in the care and treatment of preeclampsia and eclampsia, read by my former associate, Dr. John Vruwink, before this section at the Dallas session in April 1926. In that paper we reported the results of treatment in forty-five severely preeclamptic patients and 103 eclamptic patients, using the technique developed by myself and associates at the Los Angeles County General Hospital. The mortality among the eclamptic patients was 14.8 per cent, and only six of the forty-five patients with preeclampsia developed convulsions.

Several distinct clinical entities are included in the term "late toxemia of pregnancy." While fully appreciating the value of classifying the late toxemias as eclampsia, preeclampsia, chronic nephritis complicating pregnancy and low reserve kidney, as suggested by Stander and Peckham,<sup>4</sup> I agree with Plass<sup>5</sup> that it is impossible to differentiate clinically between the last three types, and I include in this study all late toxemias of pregnancy which have resulted in convulsions, or in

which at least a portion of the treatment has been directed toward the prevention of convulsions.<sup>6</sup>

The conditions indicating the necessity for treatment in this clinic may be summarized as a sustained rise in the systolic blood pressure to 135 mm. of mercury or over, albuminuria, edema, headache, visual disturbances and epigastric pain.

In general, the active treatment of the late toxemias of pregnancy has included the following principles:<sup>7</sup>

- 1 The reduction of the products of protein metabolism, in order to spare the kidneys.
- 2 The rapid elimination of the toxic elements circulating in the blood, in order to reduce the damage to the brain, heart and liver.
- 3 The administration of carbohydrates to replenish depleted stores of glycogen in the liver.
- 4 The protection of the patient from injury during unconscious periods.
- 5 The support of the cardiac and respiratory centers until the peak of the intoxication is passed.
- 6 The emptying of the uterus if the patient's condition does not improve under active treatment.

### WHAT IS MEANT BY CONSERVATIVE TREATMENT

Considerable difference of opinion exists as to the limitations of conservative treatment. When the pendulum swung from the surgical treatment of eclampsia to the medical treatment, there were many who con-

TABLE 1—Results of Treatment of Eclamptic Patients During the Radical Period 1919-1924

demned operative delivery under any conditions. Stroganoff reserves operative delivery for patients in whom intervention becomes absolutely necessary for the sake of the child. Plass, in a classic review of the subject, writes "At present, there can be no question but that the regular treatment for eclampsia should be conservative, with radical surgical procedures reserved for the unusual cases with complications which themselves afford indications for operative delivery." This statement expresses my general policy. I believe, however, that in view of the known latent effects on the mother and the high infant mortality, unless the toxemia shows definite response to ameliorative measures, systematically used over a reasonable period of time, a complication exists which may justify the termination of pregnancy. Peckham<sup>8</sup> in a review of the fetal mortality in the toxemias of pregnancy expresses my view in this regard. He says "It is generally agreed that chronic nephritis is definitely aggravated by pregnancy; the severity of the condition after pregnancy is much advanced, and the amount of renal damage is in ratio to duration to which pregnancy is allowed to continue. A considerable number of women suffering from a non-nephritic variety of toxemia will be found to have a definite chronic nephritis some months after

delivery. A high fetal mortality rate exists with all types of toxemia of pregnancy. In the cases with the severer toxemic manifestations the outlook for the child is so poor that it should have little effect upon the treatment.

While the treatment given in this clinic is generally spoken of as the magnesium sulphate treatment for eclampsia, I have never regarded the intravenous injection of magnesium sulphate as more than a very valuable

TABLE 2—Results of Treatment of Eclamptic Patients with Magnesium Sulphate from 1924 to 1934

	Number of Cases	Gross Mortality	Corrected Mortality
From May 1924 to February 1926	54	10.66%	11.5%
From February 1926 to July 1929	71	7.0%	5.7%
From July 1929 to November 1932	100	16.0%	10.6%
From November 1932 to April 1934	34	11.76%	11.76%
Total	259	12.85%	9.86%

adjunct in the commonly accepted conservative treatment of toxemia. As Lazard<sup>9</sup> states, "it is essentially a sedative, dehydration therapy" which clinically will cause considerable reduction of blood pressure, reduce edema, increase urinary output, and reduce or control convulsions and certain other symptoms. In my opinion there is a strong possibility that additional study of the pharmacology of magnesium may demonstrate properties which will fully explain the clinical effects which we have observed.

The Stroganoff treatment, sedation with morphine and chloral, with noninterference with pregnancy, is the basis of conservative treatment today. The use of chloroform, as advocated by Stroganoff, cannot be justified in view of the present knowledge that it produces central necrosis of the liver lobules. The rationale of such treatment is difficult to understand, but, as Stander states, "It has recently been shown that morphine raises the CO<sub>2</sub> combining power of the blood, and this property, together with its sedative action, may explain the good results following its use in eclampsia." Stander makes another pertinent observation relative to the mortality reported by Stroganoff, in concluding that "Stroganoff deals with mild and unneglected cases, while in most obstetrical clinics in this country the patient is usually admitted when in a desperate condition."

Titus, Dodds and Willetts,<sup>10</sup> in addition to the usual rational procedures, advise the injection of a strongly

hypertonic dextrose solution, which they state has a striking effect in controlling both the severity and the number of the convulsions as well as in lowering the blood pressure and stimulating diuresis. The basis of their recommendation lies in the contention that the principal change in toxemia of pregnancy is one of carbohydrate metabolism based primarily on a deficiency of carbohydrate intake plus increased consumption of

carbohydrate, resulting in a depletion of the glycogen stores with damage to the liver and its function. Stander and others have taken issue with Titus. An analysis of the blood sugar determinations in our cases has definitely confirmed the conclusion of Titus that in true toxemia there is a relative hypoglycemia, and I am utilizing his suggestion regarding the use of carbohydrates in all types of toxemias of pregnancy.

OBSERVATIONS ON THE PHARMACOLOGY OF MAGNESIUM SULPHATE, IN RELATION TO ITS USE IN THE LATE TOXEMIAS OF PREGNANCY

In 1905 Meltzer<sup>11</sup> demonstrated the role of magnesium sulphate in controlling the convulsions of tetanus and established its anesthetic properties. Later he amplified his original contribution.<sup>12</sup> Numerous investigators<sup>13</sup> have confirmed this, and it now seems definitely established that magnesium sulphate possesses the property of controlling convulsions in tetanus, eclampsia and certain other conditions, and that the drug possesses marked anesthetic properties.

It is well established that the intravenous injection of hypertonic solutions of magnesium sulphate will reduce both the cerebrospinal fluid pressure and the brain bulk. Postmortem studies have shown that edema of the brain, causing increase in the bulk of the brain, is an almost constant phenomenon in eclampsia, and many observers believe that increased cerebral pressure may be a cause of the convulsions.

TABLE 4—Mortality in Preeclamptic Patients Treated with Magnesium Sulphate from 1924 to 1934

	Number of Cases	Number of Deaths	Mortality
To July 1929	143	4	2.80%
July 1929 to November 1932	225	2	0.89%
November 1932 to April 1934	160	3	1.76%
Total	528	9	1.66%

Experimental evidence shows that the injection of magnesium salts either subcutaneously or intravenously is followed by a rise in blood sugar.<sup>14</sup>

Beginning with Meltzer's contribution in 1905,<sup>11</sup> investigators have rather consistently warned of the toxic effect of intravenous administration of magnesium sulphate, because of the danger of causing respiratory failure. Stander at first<sup>15</sup> considered the intravenous use of magnesium sulphate unsafe and unwarranted but later<sup>16</sup> considered that a total of 6 Gm of magnesium sulphate administered intravenously in 20 cc doses of a 10 per cent solution over a period of twenty-four hours up to a maximum of 6 Gm of magnesium is within the limit of safety. His principal objection was the production, in experimental animals, of definite histologic changes in the liver and kidneys, in the form of moderate necrosis and degeneration. Hirschfelder<sup>17</sup> calls attention to the fact that a condition of coma easily mistaken for uremic coma, can be induced in nephritic patients by purgation with magnesium sulphate.

but states that his results in no way conflict with those of investigators who have administered magnesium sulphate intravenously for eclamptic convulsions, since they gave in carefully controlled doses only sufficient magnesium sulphate to produce subsidence of convulsions

I have used magnesium sulphate intravenously in eclampsia for eighteen years, during ten years of which it has been in routine use at the Los Angeles County General Hospital. During the early experimental period,

TABLE 5—*Preeclampsia Patients Developing Convulsions While Under Treatment with Magnesium Sulphate*

	To July 1929	From July 1929 to November 1932	From November 1932 to April 1934	Total
Cases admitted in labor and given magnesium sulphate as a prophylactic	55	78	77	210
Convulsions	5	1	8	14
Cases admitted during the last 2 weeks of pregnancy and in which magnesium sulphate was the main feature of treatment	83	150	92	330
Convulsions	6	9	6	21

I was in constant fear of the respiratory failure which so many investigators had stressed. An intern, impressed only with a knowledge that doses of 20 cc of 10 per cent magnesium sulphate were used in the treatment of eclampsia, administered six doses, or 12 Gm., of magnesium sulphate within ten hours to an eclamptic patient who was in a desperate condition. She made an uneventful recovery. The incident had a direct bearing on the increase in the dosage used in the clinic. During this period we have not observed any respiratory depression or any clinical evidence which would indicate that the drug has been injurious either directly or indirectly.

Magnesium sulphate has been administered intraspinally,<sup>18</sup> intramuscularly<sup>19</sup> and intravenously. Since Dorsett's results with intramuscular injections and the results of many observers with intravenous injections have been so satisfactory, there does not seem to be any justification for the intraspinal method. Our experience in a not inconsiderable number of patients

treated by the intramuscular administration would indicate that painful induration and sloughs follow that method with sufficient frequency to make the intravenous route the method of choice.

SCOPE OF THE PRESENT REPORT

This report includes 540 preeclamptic patients, of whom thirty-five developed convulsions (6.41 per cent), and 259 patients with convulsive toxemias, a total of 799 cases. The report is a compilation of the reports of

18 Alton Botto J. Exper. Med. 25: 83 (Jan.) 1917  
19 Dorsett L. Am. J. Obst. & Gynec. 11: 227 (Feb.) 1926  
J. Missouri M. A. 27: 316 (July) 1930

Lazard,<sup>9</sup> McNeile and Vruwink<sup>3</sup> and Lazard, Irwin and Vruwink,<sup>20</sup> as well as a summary of the results obtained from November 1932 to April 16, 1934. With the exception of a limited number of cases which were either under the immediate care of a member of the obstetric staff or were seen in consultation, the cases are from my service and that of Dr. E. M. Lazard at the Los Angeles County General Hospital. The obstetric department of this hospital cares for more than 500 cases each month, of which 350 deliveries are conducted in the hospital and 150 deliveries are conducted by the outdoor service. The relative number of patients who receive adequate prenatal care is small. A large proportion of the patients treated for toxemias have had no prenatal care and are often admitted in a desperate condition. A large proportion of the convulsive conditions would be classed as "severe types" according to the classification proposed by the British Congress of Obstetrics and Gynecology in 1922, which classified as severe any case of eclampsia presenting two or more of the following signs: (1) coma, (2) pulse rate over 120, (3) temperature above 103, (4) a number of convulsions greater than ten, (5) a urine that becomes solid on boiling, (6) absence of edema, (7) a blood pressure over 200.

PROPHYLAXIS OF LATE TOXEMIAS OF PREGNANCY

A discussion of the treatment of late toxemias of pregnancy would be incomplete without mention of the

TABLE 7—*Indications for Cesarean Sections on Preeclamptic Patients*

	Cases

Toxemia of pregnancy	8

effect of prophylaxis, i. e., prenatal care. The Los Angeles Maternity Service, the outpatient division of the Los Angeles County General Hospital, caring for prenatal care and home deliveries, rarely sees a case of eclampsia in patients who have registered early in pregnancy. In addition to the usual medical supervision given generally in obstetric dispensaries, we insist on limitation of the patient's weight during pregnancy and on dental examination of all patients to discover and treat oral foci of infection. The results during the three years of dental service have had such a pronounced effect in reducing our incidence of toxemias that I feel that the necessity for stressing this phase of prenatal care is amply justified.

ROUTINE ACTIVE TREATMENT OF PREECLAMPTIC PATIENTS

1. Absolute rest in bed is necessary. Hospitalization is very desirable, but patients with mild toxemias can be cared for in the home if hospitalization is not feasible.
2. A milk diet is used. In conformity with opinions expressed by many authors regarding nephritic, basic and other diets in cases of toxemia, several types of diet have been tried from time to time. I am definitely of the opinion that from the clinical standpoint an intake composed exclusively of milk and water is advantageous.

20 Lazard E. M., Irwin J. C. and Vruwink John. Am. J. Obst. & Gynec. 12: 104 (July) 1926; Irwin J. C. ibid. 34: 208 (Feb.) 1926.

3 The fluid balance must be maintained by accurately measuring the fluid intake and output. If necessary, a retention catheter is used to insure the accurate measurement of urine excreted. Fluid bowel movements should be measured.

4 The bowels are to be kept active, 1 ounce of magnesium sulphate being given every six hours until the bowel movements are watery, then one-half ounce daily. The recent observation of Hirschfelder<sup>17</sup> that in patients with renal insufficiency the oral administration of magnesium sulphate may produce coma, but that sodium sulphate may be substituted safely in such cases, may be the basis for changing this part of our treatment.

5 A urinalysis of a twenty-four hour specimen is made daily. A quantitative estimation of the albumin is done with a routine chemical and microscopic examination.

6 The blood pressure is taken three times a day, or oftener if indicated by a rising blood pressure or other evidences of an increasing toxemia.

7 Twenty cc of a 10 per cent solution of magnesium sulphate is administered intravenously when the systolic blood pressure is 150 or higher and is repeated when indicated by a rising blood pressure or other evidences of increasing toxemia. From 60 to 120 cc can be safely given in twenty-four hours.

8 Dextrose, 300 cc of a 25 per cent solution, must be given intravenously from one to four times daily and is particularly important in patients showing decreased urinary output with or without a low carbon dioxide combining power of the blood.

9 Patients who are very restless should be given chloral hydrate, 20 Gm, and sodium bromide, 60 Gm, by rectum.

10 If the symptoms improve, we add a basic diet and place the patient on a very restricted regimen. If the symptoms do not improve, or become more severe, after a reasonable period, which, in this clinic usually varies from four to seven days, but in not exceptional cases may be continued much longer, we ordinarily induce labor by artificial rupture of the membranes, or with a Voorhees bag.

Cesarean section is rigidly reserved for cases in which it is definitely indicated for some obstetric condition other than toxemia of pregnancy, and for patients with fulminating toxemia.

#### MANAGEMENT OF THE PATIENT WITH CONVULSIONS

1 Twenty cc of a 10 per cent solution of magnesium sulphate is administered intravenously as soon as possible after the first convulsion. This dosage is repeated every hour until the convulsions are under control. The subsequent dosage is based on recurrence of convulsions, elevation of blood pressure and other signs.

2 The patient is placed in a private room. An attendant is with the patient constantly.

3 Inhalations of pure oxygen are administered to the patient after each convulsion and are continued until the respiration is normal.

4 If the patient is in labor, nitrous oxide or ethylene analgesia is given during contractions if the restlessness cannot be adequately controlled by rectal administration of chloral sodium bromide.

5 Self injury is prevented, if necessary, by using very gentle restraint during the convulsions.

6 Absolute quiet in a dark room is maintained and examinations are made only when absolutely necessary.

7 The general orders applying to the routine treatment of preeclamptic patients are continued so far as possible. The administration of dextrose is of great importance, as is also the rectal administration of chloral sodium bromide to patients who are restless.

8 If the patient is in the second stage of labor and progress is not being made, she is delivered with forceps or by other indicated procedures.

9 Cesarean section is done only for a bona fide obstetric indication or for a fulminating toxemia, and then only with the consent of the senior attending obstetrician.

#### TREATMENT AND RESULTS DURING THE FIVE YEARS (1919 TO 1934) PRECEDING THE USE OF THE MAGNESIUM SULPHATE TECHNIC IN THE TREATMENT OF LATE TOXEMIAS<sup>1</sup>

During the period of five years from 1919 to 1924, our treatment of toxemias of pregnancy consisted of the usual measures in common use at the time, such as elimination, epsom salt by mouth, hot packs, blood-letting and veratrum viride. We greatly relied, however, on the prompt delivery of the patient, particularly in the convulsive type of case. During this period of radical treatment of late toxemias, thirty-four preeclamptic and ninety-one eclamptic patients were treated.

TABLE 8—Number of Intravenous Injections of Magnesium Sulphate Administered in Recent Series of Eclamptic and Preeclamptic Patients

	Eclamptic Patients	Preeclamptic Patients
From 1 to 5 doses	8	88
From 6 to 10 doses	12	22
From 11 to 15 doses	4	14
From 16 to 20 doses	8	11
From 21 to 25 doses	1	4
From 26 to 50 doses		7
Over 50 doses		2

From 1924 to 1934 a total of 799 patients with late toxemias were treated with magnesium sulphate. Of this group 540 had preeclampsia and 259 had eclampsia.

The four deaths occurring in the more recent group were apparently due to eclampsia. All cases were of the severe type. A brief abstract of two cases, no less severe than the others, will serve as an example of the type of eclampsia which contributes to our mortality.

CASE 1—A secundigravida, aged 23, seven and one-half months pregnant, admitted Feb 22, 1934, had had no prenatal care. Convulsions had occurred three and one-half hours before admission and were controlled with chloroform by another physician. The blood pressure on admission was 160 systolic and 106 diastolic. The maximum blood pressure was 192 systolic and 134 diastolic. She was semicomatose and the convulsions were well controlled with magnesium sulphate. Labor was induced Feb 23, 1934, with a Voorhees bag. The spontaneous delivery of a stillborn, premature infant occurred seventeen hours later. The patient died twenty-four hours after delivery.

CASE 2—A primigravida, aged 33, eight months pregnant, admitted May 13, 1933, had had edema of the feet for three weeks and severe headaches for two days. She had had no prenatal care. The first convulsion occurred ten and one-half hours before admission and was followed by alternating periods of coma and convulsions. The maximum blood pressure was 200 systolic and 110 diastolic. Induction of labor by artificial rupture of the membranes was done on May 15, 1933. The patient was delivered May 18. A spinal tap, May 19, showed a spinal fluid pressure of 400 mm. The patient had been comatose for the past six days. Death occurred May 24. The

autopsy showed liver changes characteristic of eclampsia and very marked multiple cerebral hemorrhages

The methods of delivery in the thirty-four cases occurring in the more recent group are of interest

Both low cervical sections were done on primiparas with fulminating toxemia of severe type. Both patients made uneventful recoveries

We are convinced that many reports, criticizing the use of magnesium sulphate in eclampsia because of ineffectiveness, have arisen because an adequate dosage was not used. During the first five years of its use we constantly varied the dosage. It is our opinion that, in general, the dosage recommended in this paper is clinically safe and effective and that the use of smaller doses is not likely to give satisfactory results

The continued use of the drug over long periods of time in preeclamptic patients who do not show definite improvement is not to be recommended

#### INFANT MORTALITY IN ECLAMPTIC PATIENTS

In the recent series of thirty-four patients with eclampsia there occurred one pair of twins. Of the thirty-five babies, twenty-two were discharged in good condition. Two of the patients were delivered at home, and the babies were not admitted. Prematurity was the cause of four stillbirths and five deaths. Toxemia was the cause of two stillbirths. The infant mortality was 31.42 per cent

#### COMMENT

It is obvious that the entire credit for our reduction in maternal mortality which resulted from late toxemias of pregnancy cannot be attributed to the use of intravenous magnesium sulphate. The effect of eliminating radical surgery, except when clearly indicated, has been thoroughly demonstrated. Regardless of the controversy as to the exact interpretation of clinical and laboratory data, the use of carbohydrates in the treatment of toxemias of pregnancy has been the basis for the successful treatment of many severely sick patients. The favorable effect of maintaining a proper water balance in toxic patients is generally recognized. It is not my intention to give the impression that I regard the intravenous use of magnesium sulphate as any more than an extremely valuable adjunct to the commonly accepted conservative treatment. During the eighteen years in which I have used magnesium sulphate intravenously, in the latter ten years of which it has been a major part of the treatment of late toxemias at the Los Angeles County General Hospital, I have clinically demonstrated the safety of the procedure, and its effectiveness in allaying restlessness, controlling the convulsions of eclampsia and increasing the urinary output. In a very large portion of patients there is an immediate and surprising improvement in the general toxic symptoms

#### CONCLUSIONS

1 In 799 cases of late toxemias of pregnancy, 259 were of the eclamptic type

2 There was a definite decrease in the mortality in eclamptic patients treated by conservative methods at the Los Angeles County General Hospital

3 The intravenous injection of a 10 per cent solution of magnesium sulphate has proved a very valuable adjunct in our treatment of the late toxemias of pregnancy. It will cause some reduction of blood pressure, reduce edema, increase urinary output and reduce or control other symptoms

4 The intravenous injection of a 10 per cent solution of magnesium sulphate will control the convulsions

of eclampsia in nearly every case, and exercises a favorable influence on the other symptoms of eclampsia

5 The intravenous injection of a 10 per cent solution of magnesium sulphate is clinically proved to be a safe procedure

123 West Sixth Street

#### ABSTRACT OF DISCUSSION

DR. PAUL TITUS, Pittsburgh: It is apparent from Dr. McNeile's paper that he favors, as most of us do, the "conservative" treatment of eclampsia. This is not necessarily always medical, as an operative procedure, such as forceps delivery during the second stage, may be actually conservative. Dr. McNeile's point that preeclampsia and eclampsia are essentially the same disease should be emphasized. They differ only in the addition of one spectacular symptom, the convulsion, and treatment to be most successful should be begun in the preeclamptic stage. One might question the advisability of stressing a single therapeutic step in the treatment of eclampsia by speaking of it as the "magnesium sulphate treatment," because one might deduce that this constitutes the entire treatment. Dr. McNeile was careful to emphasize the other important procedures, so that this comment is no criticism of his paper. Treatment of preeclampsia and eclampsia is properly divided into three main heads. First is its sedative treatment, magnesium sulphate injections are important here but when not available the older use of morphine is still effective. Second is the supportive treatment, of which intravenous injections of hypertonic dextrose solution are an important part. The third, briefly, is the appropriate management of the pregnancy and labor, as it occurs after the first two general procedures have become effective and the patient's condition improved. It is at these times that proper obstetric intervention is no longer to be considered as being radical. The work of the California group in stressing the fundamental importance of sedation has been of great importance in reducing the mortality rate of eclampsia.

DR. ALBERT HOLMAN, Portland, Ore.: I wish to discuss the neonatal mortality associated with the toxemias of pregnancy. The autopsy reports on babies born alive of toxic mothers and dying in the first forty-eight hours were unsatisfactory, the pathologists most often being unable to determine the cause of death. Following the publication of that monumental work by Dr. Titus and his associates on the relative hypoglycemia associated with eclampsia, I felt that possibly the cause of neonatal deaths in babies of toxic mothers was hypoglycemia. My associate Dr. Albert Mathien and I determined the normal range of blood sugars in the new-born and the relationship between the blood sugar of the normal new-born and that of the mother at birth. We found that the babies' blood sugar fell into the normal adult range and that there was a very close relationship between the blood sugar of a baby and that of its mother. We felt that the babies of toxic mothers with hypoglycemia must of necessity be born with a hypoglycemia, which increased after birth because of the metabolic drain and frequently descended to a point incompatible with life. We decided that the baby should be protected at birth by prophylactic injection of concentrated dextrose into the umbilical vein. After we had treated several babies in this way we had occasion to examine the blood of an eclamptic mother and her baby taken at birth. The woman had received 300 cc of 25 per cent dextrose solution fifteen minutes before the birth of the child and at birth the blood of the mother and of the baby contained approximately 300 mg of dextrose per hundred cubic centimeters of blood. This demonstrated that dextrose given intravenously to the mother rapidly passes through the placenta into the fetal circulation. We now feel that irrespective of the amount of carbohydrate administered to the toxic mother during the course of her disease, the baby should be protected by the administration of 300 cc of 25 per cent dextrose solution to the mother shortly before delivery. The baby should receive sufficient carbohydrate by mouth after birth to protect it against hypoglycemia. We feel that in this manner the high neonatal mortality associated with eclampsia probably may be decreased.

# PROGNOSIS IN ARTERIOSCLEROTIC HEART DISEASE

L E VIKO, MD  
SALT LAKE CITY

No part of medical practice is more difficult than accurate prognosis. Yet to the patient the outlook for length of life and degree of disability is of greater interest than the technicalities of diagnosis or the details of treatment. Heart disease of any kind offers special difficulties in prognosis, and among the different etiologic types of heart disease the problem is greatest among the arteriosclerotic. Not infrequently the physician is called urgently to the bedside of a patient dying suddenly of coronary occlusion and is told by the widow that only a week or a month before a physician had examined the patient and had found no heart trouble or had said that there was "nothing serious." It is still more embarrassing beside the death bed if the same physician has given the optimistic prognosis a week or a month previously.

Since prognosis is merely quantitative diagnosis rational treatment depends on the ability to estimate the stage of cardiosclerotic process. Referring to this fact, Mackenzie said "The recognition of the true state of matters enables us to map out a plan of life for the individual." For this reason he studied a series of cases of angina pectoris to determine the possible relationship between symptoms and physical signs and length of life. While he noted that pulsus alternans, nocturnal dyspnea and Cheyne-Stokes respiration were serious signs, he concluded that the chief one was the ease with which attacks are provoked. Confronted with the all too frequent unexpected deaths, other writers have been frankly skeptical of the possibility of an accurate prognosis. Thus Brooks<sup>1</sup> states that the "prognosis is exceedingly uncertain and there are no rules or signs which permit the clinician to prognose with anything like accuracy." Sutton and Lueth<sup>2</sup> consider the prognosis of coronary occlusion "most uncertain", they predicate the future of the patient with angina pectoris on the likelihood of coronary occlusion, cardiac rupture and ventricular fibrillation and state that not one of these conditions can be definitely foretold. Vaquez<sup>3</sup> stresses the significance of intermittence or progression of the symptoms and of concomitant lesions of the liver, kidneys and arteries in the prognosis of fibrous myocarditis. Lewis<sup>4</sup> describes the usual sequence of symptoms in coronary occlusion and angina pectoris and stresses the difference in the outlook for angina of effort and angina decubitus. Eggleston<sup>5</sup> found the nature and severity of the symptoms unsafe guides in comparison with the heart's response to effort. White<sup>6</sup> studied the records of 200 patients with angina pectoris and compared the number showing certain signs or symptoms in the entire group with fifty of the group who died within five years

and with fifty of the group who were still living at the end of five years. He concluded that hypertension, coronary thrombosis, syphilis, evident arteriosclerosis, poor heart sounds, abnormal T waves in the electrocardiogram and especially cardiac enlargement were more often found in those patients with angina pectoris who died than in those who survived. He noted that as a rule the more severe the pain, the worse the prognosis and the greater the number of the unfavorable factors appearing in a given case, the worse the outlook for the patient. He found that the prognosis was fairly good if the examination, electrocardiogram and roentgen study were all negative, early death was possible in such cases but unlikely.

Most reports considering the prognosis of a series of cases of angina pectoris include not only those in which this symptom is due to coronary arteriosclerosis but also those in which it is due to rheumatic aortic

disease and syphilitic aortitis, likewise cases of coronary occlusion due to syphilis are grouped together with those due to coronary arteriosclerosis. Since it is reasonable to suppose that the etiologic factor might modify the prognosis, the present paper includes for discussion only those cases in which coronary arteriosclerosis was considered the cause of angina or coronary occlusion. Also, many cases of arteriosclerotic heart disease are included in which no history of attacks of angina pectoris or coronary occlusion could be obtained, and certain cases with a history of angina in which the predominant feature was congestive failure. No doubt in many cases the myocardial failure depended on unrecognized coronary occlusion in the past but the exclusion of such instances would give an incomplete picture of arteriosclerotic heart disease. While the series included some cases presenting hypertension, cases in which the hypertensive heart disease clearly antedated the cardiosclerosis or dominated the picture were excluded. The attempt is made to present the prognosis of cases corresponding to the pathologic sequence of coronary sclerosis (with or without occlusion) and myocardial fibrosis. From some 400 cases diagnosed arteriosclerotic heart disease, 153 meeting the

requirements named and on which adequate follow-up data were obtainable were studied in an effort to evaluate the prognostic significance of certain symptoms and signs. I examined all the patients at least once, many were followed for as long as ten years.

The great majority of the patients were seen in private practice. The records in my charity hospital service were often inadequate or the follow-up data were too unsatisfactory to justify their inclusion. Of the 153 patients, seventy-six are dead and seventy-seven are living, permitting comparison and reexamination of the living patients to help clear up questionable points.

Certain patients are included who were first seen a short time before death or were seen only in the home, so that electrocardiographic and roentgen studies were not obtainable, such patients form a considerable part of the prognostic problem presented to the physician. The diagnostic criteria were those of the American Heart Association.<sup>7</sup>

The general composition of the series is shown in table 1. The series appeared reasonably representative of urban and rural populations, the sex and age distribution was the usual one. The high percentage in occupation of business and professions naturally resulted from the predominance of private practice cases.

TABLE 2—First Symptom and Cause or Type of Death

First Symptom	Total	Cause or Type of Death				
		Group A (28)		Group B (33)		Group C (15)
		Anginal Syndrome	Congestive Failure	Cerebral Hemorrhage	Other Causes	
Angina	20	16 (80%)	2 (10%)	0	2 (10%)	
Dyspnea	27	4 (15%)	20 (74%)	2 (7%)	1 (4%)	
Dyspnea and angina	7	4 (57%)	1 (14%)	2 (28%)	0	
Dizziness syncope and so on	8	3 (37%)	0	4 (50%)	1 (12%)	
Other symptoms	14	1 (6%)	10 (73%)	0	3 (20%)	

A study of the symptomatology of those patients who had died of heart disease showed that there had been a surprising tendency for the clinical picture to follow either the anginal syndrome or the syndrome of congestive failure. Though a few cases beginning with angina pectoris changed to the picture of chronic congestive failure and cessation of angina, usually congestive failure was a terminal event. Likewise a high percentage of those cases beginning with congestive failure presented this syndrome to death without apparent angina or coronary occlusion. In a high percentage of cases the first symptom pointed to the type of death (table 2). One half of the patients in whom dizziness, syncope or numbness of the extremities was the first symptom died not of heart disease but of cerebral hemorrhage. Hence it seemed to be advantageous to study the cases in separate groups according to cause or type of death.

I do not wish by the insertion of tables to over-emphasize the value of presenting data in the form of statistics. In this regard Raymond Pearl quotes Greenwood: "There is no intrinsic merit in numbers or percentages or in coefficients of correlation, their value is in aiding us to think clearly and in compelling us to express conclusions in a language which all may master if they choose." The correlations have been compared

with the probable errors from random sampling and in certain tables the frequency distribution has been compared with the standard deviation. This means of judging the significance of the figures was especially necessary in view of the small series of cases presented, which in turn resulted from the difficulty of securing a continuous clinical picture of such cases to death.

TABLE 3—Length of Life from Onset of Symptoms

Type of Death	Cumulative Percentage of Patients Dead at End of Period Named									
	6 Mos	Years								
		1	2	3	4	5	6	7	8	9
A Anginal syndrome	20	46	50	70	86	86	93	93	93	100
B Congestive failure	7	15	42	54	64	70	73	80	91	97
C Other causes	7	20	40	53	67	73	93	93	93	100

Also it is not intended to imply any certainty of the general applicability of the data obtained. Moreover, of the living patients presenting the anginal syndrome when first seen, 70 per cent still present a predominant anginal picture, similarly, of those showing at the onset symptoms of congestive failure, only 10 per cent have anginal symptoms at the present time.

LENGTH OF LIFE FROM ONSET

The average length of life of those who died was 3.5 years from the onset of symptoms, of the living patients, 4.3 years from onset to date. For those dying of the anginal syndrome the average length of life from the onset of any cardiac symptom was 3.2 years, for those dying of congestive failure it was 4.3 years. Such averages, however, hide as much information as they yield. It was more informative to note the number of patients dead at the end of successive periods from onset of symptoms.

Table 3 shows that, of the patients dying of the anginal syndrome, one fourth were dead within six months of the first symptom, nearly one half at the end of the first year, and three fourths by the end of the third year. Only 7 per cent lived after the sixth year. In contrast, of those dying of congestive failure, one fourteenth, one sixth and one half were dead at the same intervals. In the group who died of non-

TABLE 4—Length of Life from Onset According to Certain First Symptoms

First Symptom	Cumulative Percentage Dead at End of Interval Named									
	6 Mos	Years								
		1	2	3	4	5	6	7	8	9
Angina	30	50	50	60	75	80	80	80	90	100
Dyspnea	4	18	41	60	70	70	74	92	92	96
Dyspnea and angina	14	29	57	71	71	80	80	80	85	100
Other symptoms	4	18	41	59	68	77	86	86	90	100
All symptoms	13	28	40	62	71	76	82	88	92	98

cardiac causes the length of life was similar to those dying of congestive failure.

Since a life expectancy based on death data is hardly useful in prognosis, a similar table showing length of life was based on the first symptom (table 4). Of the patients showing angina (including coronary occlusion) as the first symptom, 35 per cent died within six months and 50 per cent died within a year. This contrasts greatly with the patients in whom dyspnea was the first symptom, 4 per cent and 18 per cent were dead

7. Baunton J. H., Levy R. L., Munly W. C. and Pardee H. E. B. Criteria for the Classification of Heart Disease. New York: Paul B. Hoeber, 1928.

# ARTERIOSCLEROTIC HEART DISEASE—VIKO

at the intervals stated After the first year the first symptom did not so materially affect the length of life

## CORRELATION OF VARIOUS FACTORS WITH LENGTH OF LIFE FROM ONSET

*Sex*—In White's series of cases of angina pectoris there did not seem to be an association between sex and length of life based on the patients living or dead at the end of the five year period In the present series, while the seventh year equalized the difference, men showed a distinctly greater tendency to die early than did women (table 5) Likewise the average length of life of the men was 33 years from onset as compared with 41 for females This fact may be related to occupation

*Occupation*—From the present series it would be unsafe to attempt precise conclusions regarding the possible effect of occupation on the length of life The series was too small to yield large enough numbers in the various occupational groups to present data on the percentage dead at successive intervals Also, because of age or disability, many of the patients had retired from active occupations prior to or during the period of heart symptoms Hence only the average length of life is considered (table 6) The figures suggest a shorter length of life for farmers and unskilled laborers

TABLE 5—Sex and Length of Life from Onset

	6 Mos	Cumulative Percentage Dead at End of Interval Named									
		Years									
Men	14	31	48	63	74	81	84	87	90	98	
Women	7	14	29	36	57	57	71	93	100		
Total	13	23	45	62	71	71	81	88	92	98	
Average length of life of men	33 years										
Average length of life of women	41 years										

*Age at Onset*—There was apparently a definite correlation between the age at onset of symptoms and the length of life after onset (table 7) Comparing the age at onset of the living and dead patients, it was apparent that the former were a younger group This may have explained their greater average length of life

## CORRELATION BETWEEN CERTAIN SYMPTOMS AND SIGNS AND LENGTH OF LIFE

In many cases, signs or symptoms had been present for varying lengths of time prior to my examination of the patients, but as the time of the onset could not be established accurately in many cases, the comparative length of life is dated from the examination

*Dyspnea at Rest*—Table 8 makes a comparison of the presence or absence of dyspnea at rest in the seventy-six patients who died and the three subgroups considered separately Only one (10 per cent) of the patients, dying later of the anginal syndrome (group A) and showing this symptom at the first examination lived over a year, and 73 per cent were dead within six months, while of those in this group showing no dyspnea at rest 18 per cent lived over a year and only 50 per cent died within six months Groups B and C present similar differences in length of life for those with and without this symptom In the whole group of seventy-six patients only two of those with dyspnea at rest lived over three years, none lived over four years, and 60 per cent were dead within six months

*Angina and Coronary Occlusion*—A similar comparison of the patients with and without attacks of anginal pain at the time of the first examination is shown in table 9 It seems to show that anginal attacks occurring only on exertion did not materially shorten the subsequent length of life but that angina at rest or definite coronary occlusion did markedly shorten it

TABLE 6—Average Length of Life from Onset and Occupation

	Dead Patients	Living Patients	Total
Business	26 years	53 years	38 years
Professions	21 years	54 years	43 years
Housewives	30 years	42 years	40 years
Skilled labor	46 years	28 years	40 years
Unskilled labor	04 years	36 years	25 years
Farmers	30 years	40 years	33 years
All others	43 years	36 years	38 years

No patient with attacks of angina decubitus at the time of examination lived over fifteen months and one half of such patients were dead within six months None of the patients with coronary occlusion lived over six months There was no apparent difference in the outlook for those with substernal and those with precordial pain

*Paroxysmal Dyspnea*—In studying the subsequent length of life of the dead patients, with and without attacks of paroxysmal dyspnea (cardiac asthma) at the time of the first examination, it was noted that except in those who also had attacks of angina there was no apparent shortening of life as compared with those patients without paroxysmal dyspnea In the patients, however, who had both anginal attacks and attacks of paroxysmal dyspnea, the length of life was considerably shorter than in those with paroxysmal dyspnea alone or in those with anginal attacks (including coronary occlusion) alone No patient with both types of attack lived over a year and 67 per cent were dead within six months (table 10) In the patients in whom paroxysmal dyspnea and a recent coronary occlusion were noted at the first examination, none lived over two months and 80 per cent were dead within one month

TABLE 7—Age at Onset and Length of Life from Onset

*Heart Sounds*—If there was a correlation among those who died later between the character of the heart sounds at the first examination and the subsequent length of life, it seemed to indicate a longer life for those with poor heart sounds than those with good or increased sounds (table 11)

*Heart Murmurs*—Among the patients who died later, those with murmurs present at the first examination seemed to show a shorter subsequent length of

life, but since the opposite appeared among the living patients and since the differences were not great in either group, the presence of murmurs was considered of no prognostic significance, except in the case of those murmurs appearing after coronary occlusion.

**Enlargement of the Heart**—Comparing the presence or absence of general enlargement of the heart in the

TABLE 8—Dyspnea at Rest and Subsequent Length of Life

		Cumulative Percentage Dead at End of Period Named					Average Length of Life
		6 Mos	1 Yr	2 Yrs	3 Yrs	4 Yrs	
Group A	With	73	90	90	90	100	0.5 year
	Without	50	82	94	94	94	1.0 year
Group B	With	56	81	04	04	100	0.8 year
	Without	13	20	47	53	53	3.5 years
Group C	With	33	33	100			1.5 years
	Without	33	37	50	50	70	2.5 years
Total	With	60	80	93	93	100	0.8 year
	Without	34	50	66	68	77	2.3 years

It is of interest to note that only seven (9 per cent) of the living patients presented this symptom at the time of the first examination as compared with 40 per cent of those now dead.

dead patients, the subsequent length of life was somewhat shorter for those with general enlargement. This was true whether clinical signs or roentgen examination was used to judge heart enlargement. In table 12 the former is presented because of the large number of cases.

When, however, the comparison was made according to the degree of enlargement, the correlation was not very clear. This fact, and the fact that among the living patients with and without enlargement there was no significant difference, leads to the conclusion that not much prognostic weight should be given to this factor. There was a much more clear correlation between blood pressure and cardiac enlargement than between length of life and cardiac enlargement.

No correlation was apparent between subsequent length of life and the size of the aortic shadow at the time of the first examination.

**Blood Pressure**—There was no apparent correlation between the blood pressure level at the first examination and the subsequent length of life. Of course the drop-

TABLE 9—Attacks of Heart Pain and Subsequent Length of Life

		Cumulative Percentage Dead at End of Period Named					Average Length of Life
		6 Mos	1 Yr	2 Yrs	3 Yrs	4 Yrs	
Angina on exertion		33	52	66	66	86	2.0 years
Angina at rest		50	83	100			0.5 year
Coronary occlusion		100					3 days
No angina		38	52	70	76	81	2.0 years

Of the seventy-seven living patients five showed attacks of angina at rest and six had attacks of coronary occlusion at the time of the first examination. The average subsequent lengths of life were 1.1 years and 2.3 years respectively. However, only three have as yet lived over two years from that time and seven (60 per cent) have lived less than a year.

ping blood pressure following coronary occlusion and with myocardial failure carried a serious prognostic significance.

**Peripheral Arteriosclerosis**—There was no apparent correlation between the presence or degree of peripheral arteriosclerosis at the time of the first examination in either living or dead patients and the subsequent length of life. The exception to this lay in those patients dying of cerebral hemorrhage in whom the degree of

peripheral arteriosclerosis and the height of the blood pressure seemed related to the length of life.

**Premature Beats and Auricular Fibrillation**—Too few of the dead or living patients presented either of these disturbances of rhythm to justify evaluation of their prognostic significance.

**Peripheral Edema**—In the dead patients showing edema at the first examination, the subsequent length of life was definitely shorter than in those without edema (table 13). However, in the living patients the difference, though in the same direction, was slight and too great weight should not be given this factor. But of those dead patients showing both angina and edema at the first examination, none lived over eight and one-half months.

## ELECTROCARDIOGRAMS

With the wide variety of electrocardiographic abnormalities and the still larger number of possible combinations thereof, no correlation was attempted between the results of electrocardiographic examinations and subsequent length of life. In general, the electrocardiogram seemed of greater value in diagnosis than in prognosis. Certain observations, however, seemed worth

TABLE 10—Paroxysmal Dyspnea and Subsequent Length of Life

		Cumulative Percentage Dead at End of Period Named						Average Length of Life
		1 Mo	6 Mos	1 Yr	2 Yrs	3 Yrs	4 Yrs	
Paroxysmal dyspnea with angina		33	67	100				0.4 year
Paroxysmal dyspnea without angina		0	0	40	60	80	100	2.2 years
No paroxysmal dyspnea		26	40	66	70	74	84	1.8 years
Angina without paroxysmal dyspnea		34	55	71	82	82	90	1.2 years

Of the four living patients with paroxysmal dyspnea and angina only one has as yet lived more than a year and that one is bedridden with anginal failure. Of the dead patients showing at the first examination both dyspnea at rest and attacks of paroxysmal dyspnea only one lived over a year whether or not angina was present.

noting. Only slurring or splintering of the QRS, inversion of T waves and abnormalities of the RT or ST interval seemed significant, among the dead patients these observations were noted only in those subsequently dying of coronary occlusion, angina pectoris or cerebral hemorrhage and not in those dying of congestive failure. In the living patients all such observations except T wave inversion occurred among those having the anginal syndrome.

The observations thus far presented pointed out the marked tendency for patients to follow from the onset to death either the anginal or the congestive syndrome except for these few patients dying of causes other than cardiac. It has been noted that the patient following the anginal syndrome had a shorter length of life than those with other syndromes. It has been suggested that for women the average length of life was about one and one-fourth longer than for men and the probability of dying within the first three years was about one-half as great, that hard physical labor reduced the life expectancy, and that there was a progressive diminution of life expectancy as the age at onset increased. It has been suggested that dyspnea at rest, angina at rest, coronary occlusion and paroxysmal dyspnea when associated with angina decreased the life expectancy. Of less weight but of possible significance in the same direction were enlargement of the heart and peripheral

edema In the electrocardiogram, QRS and ST changes pointed toward an anginal death

Table 14 is presented not as a formula for estimating the length of life in all cases of arteriosclerotic heart disease but as a summary of certain data in this particular series

In view of Mackenzie's<sup>8</sup> remark that statistical methods may be used to prove unreasonable associations

TABLE 11—Heart Sounds and Subsequent Length of Life

	Cumulative Percentage Dead at End of Period Named						Average Length of Life
	1 Mo	6 Mos	1 Yr	2 Yrs	3 Yrs	4 Yrs	
Poor sounds	20	37	50	70	72	82	1.8 years
Good or increased sounds	30	53	60	82	88	94	1.2 years

The living patients seemed to show the same correlation

of clinical phenomena, this question should be raised here. However, the correlations made seemed to be reasonable ones. Thus it is logical to suppose that age at onset, sex and occupation would modify the length of life in any patient with heart disease. Likewise it seems logical that such signs and symptoms of myocardial failure as dyspnea at rest, paroxysmal dyspnea

TABLE 12—Enlargement of the Heart and Subsequent Length of Life

	Cumulative Percentage Dead at End of Period Named						Average Length of Life
	1 Mo	6 Mos	1 Yr	2 Yrs	3 Yrs	4 Yrs	
Enlargement	21	48	61	82	88	91	1.4 years
No enlargement	20	39	59	61	64	77	2.2 years

and peripheral edema would be significant. Likewise in the absence of a satisfactory means of estimating the extent of coronary sclerosis, angina at rest and coronary occlusion may serve as one means of measurement.

Nevertheless, granting the significance of the comparisons made, figures on average length of life or even on the probability of death within a given period are none too helpful in the prognosis of a given case, unless the data presented coincide to a reasonable degree with that of the cases showing especially long or short duration of life. When the records of the individual patients, living and dead, were rechecked, it was found

TABLE 13—Edema and Subsequent Length of Life

	Cumulative Percentage Dead at End of Period Named						Average Length of Life
	1 Mo	6 Mos	1 Yr	2 Yrs	3 Yrs	4 Yrs	
Edema present	30	61	77	80	88	92	1.0 year
Edema absent	24	34	50	66	72	82	2.1 years

that very few of those with a long duration of life after the first examination showed at that time the serious prognostic symptoms or signs and that with the later appearance of such signs or symptoms, the subsequent course followed the prediction reasonably well. Likewise, the majority of the patients with a short length of life after the first examination showed

at that time one or more of the symptoms or signs stressed and usually the larger the number present, the shorter the duration. Obviously the correlation was far from absolute but it seemed sufficient to provide valuable prognostic data.

Generally speaking, the course of those cases showing the syndrome of congestive failure did not differ a great deal from that of congestive failure due to other etiologic factors except in its shorter duration.

Other factors, not susceptible of statistical evaluation, seemed to enter into prognosis, such as the degree of signs and symptoms, the cooperation with and response to treatment and the presence or absence of other diseases.

#### PREDICTABILITY OF SUDDEN DEATH

Even more urgent a problem than the length of life of the average patient is the question to what extent the sudden deaths from coronary occlusion can be foreseen. Of my patients dying suddenly of coronary

TABLE 14—Summary of Certain Prognostic Data

	Over Length of Life from Onset	Probability of Death Within Period Named				
		6 Mos	1 Yr	2 Yrs	3 Yrs	4 Yrs

Edema present	1.0 year	61	77	80	88	92

\* Angina as first symptom makes an anginal death a 4 to 1 probability. Electrocardiographic changes in the QRS or the ST interval make anginal death probable.

occlusion, all except two gave clear histories of previous symptoms for four weeks to years preceding the fatal attack. The two patients with no such history were seen within twenty-four hours of death at a time when they were so ill that no careful history was possible. All of the patients in whom electrocardiograms were taken except one showed changes in the QRS or ST or both. No patient dying of coronary occlusion on whom a complete examination and history with electrocardiogram and roentgen study had been obtained prior to the occlusion failed to show at the examination a positive result in at least one field—a significant symptom, a physical sign or a positive instrumental observation.

The pathologist shows that the fatal coronary occlusion is not often the first occlusion or that there is usually a preceding extensive coronary sclerosis and myocardial fibrosis. Is it not possible that the apparent unpredictability of sudden deaths lies more in either

<sup>8</sup> Mackenzie, James. Principles of Diagnosis and Treatment of Heart Disease. London: Oxford University Press, 1918.

the failure of the patient to interpret the symptoms as sufficiently serious to warrant consultation with a physician or in the incompleteness of the average examination than in the insufficiency of the physician's prognostic armamentarium? Perhaps more should be done to educate the man over 50 years of age in the significance of certain symptoms and urge that at 50 a complete examination, including an electrocardiogram, dissociated from questions of insurance or employment, might at least show danger signals if it did not prolong life

#### SUMMARY

In the present paper I have attempted to evaluate certain prognostic data in arteriosclerotic heart disease. While the incompleteness of the data presented is recognized, a plea has been made against an undue attitude of hopelessness in approximating the outlook for this type of heart disease

Deseret Bank Building

#### ABSTRACT OF DISCUSSION

DR. WALTER L. BIERRING, Des Moines, Iowa. Dr. Viko's criteria with reference to prognostic significance seem to be based on two facts: the development of anginal symptoms and those of visceral congestion, both in a sense representative of a terminal stage. It is safe to assume that a rather long period of anatomic change has preceded the first recognition of these symptoms which makes it difficult to determine just when the process begins and what meaning can be placed on certain disturbances that occur during the course of so chronic a process. Arteriosclerotic heart disease, while accompanied frequently by coronary occlusion, does not appear to have the prognostic significance in later years that it might have when such an occlusion occurs in earlier life. It is generally thought that during the gradual narrowing of the arteries and the branches of the coronary there will be intermittent attacks of angina, but at the same time a gradual collateral circulation is brought about, which promotes a certain improvement in the coronary circulation. Thus one finds instances in arteriosclerotic heart disease in which the anginal attacks gradually become less, or at least less severe, indicating the difficulty to recognize and interpret anatomic changes in the myocardium and to what extent these may be developing. It is timely to refer to certain racial and vocational influences on the development of arteriosclerosis, which modify to a certain extent one's conception of the disease. The racial characteristic of the Negro toward arteriosclerosis is well known. Having lived for many years in a region rich in bituminous coal deposits, I have come to recognize arteriosclerosis at a much earlier age. There can be no doubt, and this seems to be confirmed by similar observations in the coal districts of Wales and northern England, of the greater tendency in coal miners toward thickening of the arteries in the young adult. Soon after a year's exposure to underground life, a thickening begins to manifest itself. In the Mississippi Valley, where coal deposits are extensive, it is frequently noted that the average coal miner at 55 looks as if he had finished his allotted three score and ten. The frequency of death in coal miners from arteriosclerotic heart disease after 55 is so common as to permit its consideration as an occupational disorder. This is thought to be largely due to the alteration of the atmosphere, particularly the content of carbon dioxide, and the absence of daylight. It is also interesting that at the International Conference on Geographic Pathology the latter part of July in Utrecht, Holland the main subject is arteriosclerosis showing that it is becoming recognized as peculiar to certain geographic areas. The difficulty of properly interpreting certain prognostic signs is becoming more evident.

DR. R. WESLEY SCOTT, Cleveland. Although the term arteriosclerotic heart disease is gaining in popularity, certain objections to its use are apparent. A patient with vascular disease—arteriosclerosis—may or may not develop signs of

myocardial insufficiency. If he does, two factors appear, which singly or combined may ultimately lead to heart failure. These are hypertension and coronary disease. Why not then use the term hypertensive heart disease to designate that group of patients dying of heart failure whose clinical course is dominated by hypertension, and the term coronary disease for that group (with or without hypertension) whose heart failure is more clearly associated with muscle damage secondary to coronary artery sclerosis and whose clinical course is often characterized by angina pectoris, coronary thrombosis or both? Such a classification is more easily comprehended by students and more likely to lead to straighter thinking in the therapeutic management of patients. Dr. Viko feels that prognosis in arteriosclerotic patients with cardiac symptoms is not so uncertain as many believe, but the average age of his series of 150 patients was 67.5 years. In other words, the majority of his patients survived seven and one-half years longer than the average American at the present time. Human arteriosclerosis is notoriously capricious in its distribution, and so long as there is no direct means of knowing the state of the coronary arteries, the prognosis will necessarily remain uncertain. Even in hypertensive cases the future, so far as the heart is concerned, is determined by the state of the coronary vessels in the majority of instances. In a large series of autopsies on patients dying of hypertension I have been impressed by the relation between the heart weight and the state of the coronary arteries. Patients who survive long with hypertension and develop heavy hearts (from 600 to 700 Gm.) are in the great majority those in whom the coronary vessels are less seriously diseased than those persons who succumb with a heart weight of from 400 to 500 Gm. It seems to me that the most certain feature of prognosis in so-called arteriosclerotic heart disease is its uncertainty.

DR. LOUIS E. VIKO, Salt Lake City. I do not wish to overemphasize the value of presenting data in the form of statistics. As Raymond Pearl quotes Greenwood, "There is no intrinsic merit in numbers or percentages or in coefficients of correlation. Their value is in aiding us to think clearly and in compelling us to express conclusions in a language which all may master if they choose." The correlations have been compared with the probable errors from random sampling and in certain tables the frequency distribution compared with the standard deviation. This means of judging the significance of the figures was especially necessary in view of the small series of cases presented, which in turn resulted from the difficulty of securing a continuous clinical picture of such cases to death. Also it is not intended to imply any certainty of the general applicability of the data obtained. But even granting the significance of the comparisons made, figures on average length of life or even on the probability of death within a given period are none too helpful in the prognosis of a given case unless the data presented fit reasonably well the cases with especially long or short duration. When the records of the individual cases were rechecked, it was found that very few of the patients living or dead, with a long length of life after the first examination showed at that time the serious prognostic symptoms or signs noted, and that with the later appearance of such signs or symptoms the subsequent course followed reasonably well the prediction. Likewise, the majority of the cases showing a short length of life after the first examination presented at that time one or more of the symptoms or signs stressed, and usually the more such present, the shorter the duration. Obviously, the correlation was far from absolute but seemed sufficiently so to provide valuable prognostic data. It was particularly interesting to compare the cases in which death occurred from coronary occlusion with those cases in which attacks of coronary occlusion were apparently as severe and yet the patients lived, or with the patients dying of the anginal syndrome. Seven died sudden deaths from coronary occlusion. In varying degree, these were unexpected because of their almost instantaneous character. It is noticeable that all these patients except one had been having angina at rest without dyspnea for days to months before the final attack. Likewise, five of the seven had signs of myocardial failure, such as attacks of paroxysmal dyspnea, liver enlargement or edema previous to the attack.

# OVARIAN CYST

REPORT OF AN UNUSUAL CASE WITH RECOVERY  
FOLLOWING OPERATION

WILLIAM K. LLOYD, MD

A M SHOWALTER, MD

AND

J G DAVIS JR., MD

CHRISTIANSBURG, VA

During the past decade it has become rare to encounter cases of abdominal tumor weighing 50 pounds or more. Occasionally, in the past, enormous fibroids and other tumors of the female genital organs were seen, but progress in medicine and surgery has been such that now most cases are detected and treated before any tumor reaches the 50 pound stage. In a review of the literature we have been unable to find a case of ovarian cyst with recovery approximating the one reported here. The tumor weighed about 175 pounds (80 Kg). There have been two cases of cystic ovaries reported larger than this one, both during the nineteenth century. One occurred in Europe<sup>1</sup> in 1890 and the other<sup>2</sup> in Baltimore in 1834. However, the former patient died after operation and the latter was discovered only at necropsy.

## REPORT OF CASE

*History*—Mrs J H K, aged 47, was first seen at home, April 6, 1934. Until this date, no physician had seen her since

tive except that all members for two generations have been obese. She had never had a serious illness or operation of any kind. She had consistently refused to consult a physician until this date, and then only because she had suffered all night from shortness of breath.

The patient was in bed, lying on her right side. The respirations were labored. She declared she could not lie on her back.

Fig 2—Front view. The lower end of the abdominal wall extended as low as the knee joints.

Fig 3—Just before operation four days after admission. The abdomen was pendulous after the removal of 16½ gallons of fluid.

Fig 1—Lateral view of patient on day of admission. Shrinkage of the skin of the thighs (the patient previously had very obese legs) and enlarged superficial abdominal vessels are shown.

and had not been able to do so for two years. She stated that she could lie on either side but that it had become necessary at night to have members of the family "lift her stomach" from one side to the other. When erect the patient had been able to move about freely and had performed almost all of her housework except washing, and said that she would have done that but couldn't get close enough to the tub.

There was a loud systolic murmur heard best at the apex. The blood pressure was 158 systolic, 112 diastolic. The menstrual history was normal until fourteen months before, when the menses ceased for nine months but had resumed and had been regular for the past three cycles.

The following day the patient was admitted to the hospital. Her chief complaint was shortness of breath. She had been unconscious of any enlargement of the abdomen until about five years before.

*Examination*—The patient weighed 295 pounds (134 Kg). The temperature was 100 F. The pulse rate was 100, the respiratory rate 28. The blood pressure was 170 systolic, 110 diastolic. Moist rales were heard at the base of both lungs. The heart beats were irregular and there was a loud systolic murmur. The abdomen was enormously distended and was flat on percussion. Bimanual examination was impossible. Large varicose veins on both legs and on the abdominal wall were noted.

The urine was amber colored, cloudy, and acid in reaction, the specific gravity was 1.020, it showed albumin, 3 plus, and was negative for sugar. The microscopic examination showed hyaline casts, 3 plus, occasional granular casts, epithelial cells, 3 plus, pus cells, 2 plus.

the birth of her only child twenty years previously. There were no miscarriages or abortions. The family history is negative.

<sup>1</sup> Buffet. Colossal Cyst of the Ovary. *Normandie med* 5 19 (May 19) 1890.  
<sup>2</sup> Heintze F E B. *N Am Arch M & S Sc* 1 3 1834 1835.

The blood examination showed hemoglobin 75 per cent, erythrocytes, 3,500,000, leukocytes, 8,000, small lymphocytes, 20 per cent, polymorphonuclear neutrophils, 80 per cent

A preoperative diagnosis of ovarian cyst was made. Ascites was considered but was ruled out by the absence of edema of the extremities.

**Operation and Result**—Under local anesthesia a trocar was passed through the abdominal wall, a number 16 French catheter was inserted, the trocar was withdrawn, and the skin and fascia closed firmly around the catheter. This method permitted very little leakage. Two gallons of dark fluid was withdrawn, which on laboratory examination showed disintegrated blood cells, the tube was clamped. The lower portion of the chest and the upper part of the abdomen were taped with adhesive plaster. A firmly fitting abdominal binder was applied and carefully tightened after each withdrawal of fluid. April 10, a total of 16½ gallons of fluid, carefully weighed

from the hospital to a waiting car. At this time her weight was 132 pounds (60 Kg).

Five days later she returned for dressing of the wound and walked into the hospital unassisted. Both wounds had healed and there was a definite shrinkage of the excess skin. Her weight was 143 pounds (65 Kg). She stated that she would never consent to an operation for removal of the excess skin, saying "If they give me enough to eat, I'll need all of it." The urinalysis was negative and the systolic murmur had disappeared. May 16 she weighed 146 pounds (66 Kg). When last seen, May 24, she weighed 149 pounds (67.6 Kg).

#### COMMENT

This case is interesting because of the enormous size of the tumor and the unusual recovery. We feel that the gradual withdrawal of the fluid together with a compression binder was a life saving measure. The use of spinal anesthesia together with the excellent resistance of the patient played a part in the successful outcome.

115 West Main Street

Fig 4.—Front views of patient fourteen days after operation. A with binder, B without binder.

and measured, had been withdrawn. April 12, under spinal anesthesia, the collapsed cyst was delivered through a 5 inch incision. It had originated from the right ovary, to which it was attached by a pedicle about 2 inches wide. The uterus was normal in size and was prolapsed. The left tube and ovary were normal. The cyst and approximately 2 quarts of free fluid in the peritoneal cavity were removed. Two small fibroid tumors on the anterior wall of the uterus were removed and the uterus was suspended.

The gallbladder was very much enlarged. A second incision was made over the gallbladder region. As it was deemed advisable to expedite the operative procedure, a simple drainage was instituted. Forty-one gallstones, about one-fourth inch in diameter, were removed.

The cyst wall weighed 27 pounds (12 Kg) and the patient's weight following operation was estimated to be 120 pounds (54.4 Kg). The patient was apparently entirely free from pain and shock during the operation. She had the general diet on the third postoperative day and noticeably began to increase in weight. The sutures and gallbladder drain were removed on the tenth day. She sat in the wheel chair on the eleventh day and on the fifteenth day with assistance walked

## ALLERGIC RESPONSE TO DUST OF INSECT ORIGIN

HOWELL RANDOLPH, M.D.

PHOENIX, ARIZ

This paper deals with a source of atopy in the group of insect emanations not hitherto demonstrated. The allergic response was observed in persons working on the control of the New Mexico range moth caterpillar and was acquired after contact with the eggs and parasite flies.

There have been a number of recent contributions to the subject of insect allergy. Insect dust sensitization was reported in 1928 by Vaughan,<sup>1</sup> who found an allergic response to moth dust contained in feather pillows. Parlato<sup>2</sup> in 1929 established the etiologic relation of caddis fly emanations in a patient with seasonal asthma and hay fever. The distressing symptoms occur when the patients go to the lake shore during the caddis fly season. Negative pollen reactions resulted in the search which revealed the excitant in the fine hairs and epithelia shed by the fly. Positive skin reactions and passive transference of sensitization together with successful hyposensitization were reported. One hundred and ninety-two known allergic cases were tested, with a positive reaction in 72 per cent. In a recent article he<sup>3</sup> reported thirty-two such cases treated, with good results.

Figley<sup>4</sup> in 1929 successfully treated one patient with asthma with an extract of the May fly, the preparation being made from the shed skins of the subimago stage.

Benson and Semenov<sup>5</sup> made a study of extracts of the bee's body and its sting on a bee keeper with hay fever and asthma. It was found to be (apparently) the exclusive cause of the symptoms, and they brought about relief of the asthma by increasing the patient's tolerance both to the dust as an inhalant and to the bee's sting.

1 Vaughan W T. Some Causes for Failure in Specific Treatment of Allergy. *J Lab & Clin Med* 13: 955 (July) 1928.

2 Parlato S J. Case of Coryza and Asthma Due to Sand Flies (Caddis Flies). *J Allergy* 1: 35 (Nov) 1929.

3 Parlato S J. Hypersensitivity to the Emanations of Caddis Flies (Trichoptera). *J A M A* 102: 910 (March 24) 1934.

4 Figley K D. Asthma Due to the Mayfly, *Am J M Sc* 178: 338 (Sept) 1929.

5 Benson R L and Semenov H. Allergy in Its Relation to Bee Sting. *Allergy* 1: 105 (Jan) 1930.

Without investigation as to the exact nature of the phenomena, in 1915 Mr Caffrey<sup>6</sup> observed that continual contact with eggs and larvae of the New Mexico range moth had produced a tendency to violent attacks of coughing and severe wheezing, which sometimes lasted for several days. He also noted that coryza appeared in many helpers who had worked with the eggs and larvae for a few months and that the violence of the urticarial reaction produced by contact with the caterpillar spines became much more marked after handling them for succeeding seasons.

#### REPORT OF CASE

The case of bronchial asthma here reported was caused by daily contact with these products in the work of controlling the New Mexico range moth caterpillar. The patient had been working on the problem since 1930. The chief complaint was sneezing and coryza, nocturnal dyspnea and wheezing.

There was no history of allergic disease in the family.

The patient had had malaria in 1916 and typhoid during his youth. In July 1929 he was seen for an acute respiratory infection with a temperature of 102 F, chills, general malaise, and dry cough, no dyspnea and no sibilant rales were noted on physical examination. The blood showed moderate leukocytosis with 6 per cent eosinophilia. Fresh stool examination was negative for parasites.

#### Reactions to Dust Specimens Collected from Patient's Laboratory

Dust Specimen	Reaction
1 Freshly collected and killed fly <i>Anastatus semi flavidus</i> Gahan (parasite fly)	Negative
2 Unparasitized eggs of the range moth <i>Hemileuca oliviae</i> , Cockerell	0.75 cm ++
3 Old dry wings of the New Mexico range moth	Negative
4 Dust from the floor of the laboratory	2 cm ++++
5 Dust from the floor of the incubation cages in which the parasitization process took place	1.8 cm ++++
6 Combined May fly extract furnished me by Parlato of Buffalo	1.8 cm ++++

Feb 2 1933, the patient was examined in the office because of coryza, wheezing, coughing and dyspnea. The coryza had been present to some extent since shortly after he began to work on the range caterpillar control problem but had been considerably worse during the last two years, the symptoms showing slight exacerbation during the winter months.

Nocturnal asthmatic breathing and cough had been present almost continuously since September 1932. During that month he had been working in the laboratory at Tempe, Ariz., but he had spent the month of October on the range in New Mexico, at an altitude of more than 5,000 feet gathering some eight million range moth eggs. He came back to Tempe, where he had spent several hours a day since November in the small poorly ventilated incubation room in which the eggs, larvae and parasite fly *Anastatus semiflavidus* (Gahan) were housed, stringing eggs on wires and placing them in incubation cages with the parasite flies. The parasitized moth eggs are shipped to the range, where they are allowed to propagate the parasite fly.

The patient was exposed to inhalation of the fine dust from dried specimens of eggs in the various stages of parasitization and emergence and to the dust of the empty shells of eggs from which a few of the range moth larvae emerged. He handled very few of the range moths, as the only specimens in the laboratory were kept in tightly covered boxes. Sometimes a few of the larvae of the range moth were hatched but were destroyed. Many of the parasite flies were hatched, to be used in parasitizing other moth eggs. In transferring these tiny flies a suction bottle was used, the fly being drawn into the bottle by placing the opening of the tube in its vicinity, then drawing on the other tube. In this way he inhaled much dust from the floor of the incubation cages.

On physical examination the patient was tall and slender and not in robust health. The temperature was 98.6 F, pulse 80, height 6 feet 1 1/4 inches (186 cm), and weight 156 pounds (70.8 Kg). The nasal mucous membranes were markedly thickened and injected. The pharynx was normal. The heart sounds were clear and normal. The lungs showed numerous scattered sibilant rales over the bronchial areas both front and back. Fluoroscopic examination revealed no evidence of infiltrative lung changes. The heart shadows were normal. The abdomen and extremities were normal.

#### SKIN TESTS

The common pollens of this vicinity by both scratch and intradermal methods were found to be negative. Dust specimens were collected from the patient's laboratory, and Coca's solution extracts were prepared from material obtained as shown in the accompanying table.

Ventilation of the laboratory was through a small floor ventilator only, so that outside dust was kept at a minimum. In order to determine more conclusively the source of the atopy, skin tests were made with Coca's solution extract of larvae hatched in a cotton stoppered test tube and the empty egg shells after emergence of the larvae. These produced the strongest skin reactions.

February 27, 0.03 cc of a 1 to 500 by weight solution extract of combined larvae and egg shell dust with an equal dose of the combined fly atopy furnished by Parlato was given. Intracutaneous injections were continued three times a week for two weeks, the dose gradually being increased. After the third injection the patient had a reaction within an hour after the treatment, wheezing and coughing were similar to that which had occurred at night, and there was a more marked local reaction than usual. On two other occasions, mild reactions of a similar nature were experienced. After two weeks the patient received 0.15 cc of my extract about once a week. Each intradermal injection resulted in an urticarial welt about 3 cm in diameter and in swelling of the arm from 3 to 4 inches along the arm, and the thickening remained for a day or two. Within two weeks after these injections were begun the nocturnal wheezing and coughing ceased. There was very definite improvement in the rhinitis, although not complete relief. The patient has continued at the same work since February and has been practically free from symptoms. During the summer and fall the injections were given at intervals of three weeks. There was a slight return of wheezing during October for three or four nights. These symptoms were quickly controlled by increasing the frequency of the injections.

Passive transference was demonstrated by sensitizing a non-allergic skin with 0.1 cc of the patient's serum. One week later New Mexico range moth caterpillar extract gave a positive reaction at this site, whereas the control reaction was negative. Retesting this skin area one week later gave a negative reaction, showing rapid desensitization.

Of thirty hay fever patients tested to the extract, two were found to show a two plus reaction, the others a negative reaction. One individual in occasional contact with the laboratory was found to react negatively. One man who has been working for about two years under essentially the same conditions began to have slight hay fever symptoms shortly after beginning his work. He was found to give a four plus reaction to the extract. His symptoms were hardly distressing enough to bring him under treatment, but during October 1933, while he was collecting eggs and specimens, asthma developed.

#### CONCLUSIONS

This work demonstrates the presence of atopic substances in the coverings of the New Mexico range moth caterpillar, in the spines of the larvae and in the material left behind in the egg shells after emergence of the larvae, capable of producing hay fever and asthma in an entomologist whose work required con-

<sup>6</sup> Caffrey, D. J. *J. Econ. Entomol.* 11: 363 (Aug.) 1918.

tact with the offending substance. Successful hypo-sensitization therapy was carried out.

Few allergic individuals give a weak positive reaction to this substance.

## Clinical Notes, Suggestions and New Instruments

### AUTOMOBILE JACK FOR FRACTURED SPINE

EDWIN W. RYERSON, M.D., CHICAGO  
Professor of Orthopedic Surgery, Northwestern University  
Medical School

This apparatus provides a cheap and remarkably efficient means of producing any desired degree of hyperextension of the dorsolumbar spine and makes easy the application of a

Fig 1—Materials for making apparatus

plaster-of-paris jacket in dorsal recumbency. It is particularly valuable in the forcible correction of compression fractures of the spine. It is a combination of an ordinary automobile screw-jack with a simple device that I<sup>1</sup> described in 1907. Two short pieces of half inch gas pipe, 2 inches long, are brazed vertically to the top of the jack, about an inch apart. Four flat strips of iron measuring  $\frac{1}{2}$  by  $\frac{1}{8}$  by 4 inches are bent at the middle to a right angle and two of them are slipped into each gas pipe (fig 1). This makes two T shaped supports on which will rest the kyphosis, protected by a thick piece of felt 4 or 5 inches square. The head and shoulders rest on

Fig 2—Patient supported by apparatus

boxes, and the buttocks and legs are similarly supported, padded with pillows or folded blankets (fig 2).

A stockinet undershirt has been previously applied and feet pads are placed over the anterosuperior spines of the ilium

An anesthetic, if necessary, is administered. The jack is now elevated as far as the operator desires and will produce any degree of hyperextension. A "dinner pad" is advisable over the epigastrium in cases in which extreme hyperextension is used and can be removed through a good sized window in the cast. Sheet wadding or other padding can be applied at the operator's discretion.

Plaster-of-paris bandages are now wound around in the ordinary way and reinforced by a couple of longitudinal folded strips or Soutter "ropes" in front and back. When the plaster has set, the patient is lifted up and placed face downward on a bed or cart (fig 3). The four small angle irons will be

Fig 3—After plaster has set

found projecting through a hole in the back of the cast and can easily be pulled out.

This apparatus can be used equally well in cases of Pott's disease and for some cases of scoliosis.

The cost was \$3 for the jack and \$1.50 for brazing on the pipes and making the angle irons.

122 South Michigan Avenue

### AN INSTRUMENT FOR HEMOSTASIS OF THE SCALP

PERCIVAL BAILEY, M.D., CHICAGO

Surgeons have long sought for a satisfactory method of securing hemostasis of incisions in the scalp. The one almost universally adopted in the United States employs hemostats,

Instrument for the rapid application of Michel clips

which are placed on the galea and curled backward over the scalp. This method is satisfactory for the outer margin of the incision of the ordinary osteoplastic craniotomy, but on the inner margin the hemostats are very much in the operator's way, fall into the wound and generally cause much nuisance and loss of time. Various types of clamps have been devised from time to time to replace the inner row of hemostats but have never been entirely satisfactory. The ordinary Michel clips work very well and do no damage to the edge of the skin but have heretofore been difficult and tedious to apply. I was therefore much pleased to find an instrument in use by Dr. Clovis Vincent of Paris which permitted the rapid application of Michel clips.

The instrument, which is manufactured by M. Haran, 40 rue St. Jacques, Paris, France, feeds a magazine of Michel

clips into the jaws of a thumb-forceps as rapidly as the surgeon can work his fingers. It worked perfectly for any incision on which the instrument could be held perpendicularly but failed to work well on incisions of the scalp, because the clips fed into the forceps by gravity. To obviate this defect, Mr. C. Ridet of the Yerkes Observatory devised a rider and ratchet, which is attached to the top of the instrument. The magazine kicks backward from under the rider, which retains its place by inertia and thus keeps the clips feeding into the jaws of the forceps when held in any position. The instrument is now quite satisfactory and rapid in action and the heavy hemostats no longer give trouble.

The instrument is shown in the accompanying illustration  
950 East Fifty-Ninth Street

#### THE ARTHUS PHENOMENON REPORT OF A CASE

FRED E. ROSS, M.D., ERIE, PA.

A local necrosis following infrequently repeated subcutaneous injections of horse serum was first noted by Arthus experimenting with rabbits, in 1903. He described the occurrence of a characteristic set of symptoms which has since been known as the Arthus phenomenon. The symptoms seem to be due to an anaphylactic reaction of antibodies with a specific antigen, which results in the formation of a toxic substance causing local necrosis in the tissues. The reaction is specific for the antigen used.

Since the publication of these and other studies, clinical instances of the Arthus phenomenon have been recorded in the literature with increasing frequency. The results of an exhaustive study of the clinical and serologic aspects of the condition have been reported by Tumper and Cope.<sup>1</sup> A case exhibiting this phenomenon is here reported.

A boy, aged 4½ years, had been given toxin-antitoxin for diphtheria immunization a year previously. November 22, he sustained a scalp injury and the attending physician administered a prophylactic injection of tetanus antitoxin. Three days later he had a temperature of 104 F., a generalized erythematous rash, vomiting and a sore throat with cervical adenitis. The symptoms so closely resembled those of scarlet fever that the physician administered a therapeutic injection of scarlet fever streptococcus antitoxin in the buttock. The efflorescence cleared up in a few hours, but the site of the injection immediately became indurated and erythematous and a lesion developed which spread with such fulminating intensity that when seen December 1, the skin and subcutaneous tissues of the entire thigh, hip and abdomen were involved in a huge necrotic sloughing mass. The patient died as the result of sepsis that evening. Permission for an autopsy was not obtained.

Clinical instances of this phenomenon demand attention and consideration for at least two reasons: first, they stress the importance of the use of toxoid, which contains no serum, instead of toxin-antitoxin as an agent for immunization against diphtheria and, second, they show that the greatest caution must be used in the administration of any type of serum to a patient showing symptoms that might possibly be manifestations of anaphylaxis.

<sup>1</sup> Tumper, I. H., with the technical assistance of Cope, Elizabeth J., The Arthus Phenomenon. A Serologic Study in a Syphilitic Child with a Fatal Reaction to Transfusion. *Am. J. Dis. Child.* 45: 343 (Feb.) 1933.

**Scientific Methods a Modern Development**—Let me remind you that the general use of exact scientific methods in medicine is quite a modern development. It is hardly more than a hundred years ago that such simple methods as percussion and auscultation came into common use. Auenbrugger was alive at the beginning of the nineteenth century, and Laennec did not die until 1826. Even so simple an instrument as the clinical thermometer, occasionally used in a primitive form as early as the seventeenth century, did not come into general use until after the publication in 1868, of Carl Wunderlich's treatise on bodily heat in relation to disease.—Blumer, George. Some Discursive Remarks on Bedside Diagnosis, *Yale J. Biol. & Med.* 6: 571 (July) 1934.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
H. A. CARTER, Secretary

### ALTHERM EYE PAD ACCEPTABLE

The E. B. Mcyrowitz Surgical Instruments Company, Inc., New York City, recommends the Altherm Eye Pad as a convenient device for applying heat to the eye.

The term "Altherm," according to the firm, is a coined name. The syllable "Al" was taken from its trade mark "ALPHA" (rubber products) and "Therm" to indicate its heating properties.

The mixture (heat-retaining element) used in the pad is nonirritating and nonflammable. When the pad is boiled for a short time, the contents liquefy. After removal from boiling water and in ordinary room temperatures the mixture gradually recrystallizes as it gives off heat. The action makes use of the latent heat of crystallization. The contents do not need renewing after each time the pad is used.

The total weight of the thermophoric mixture amounts to about 4 ounces avoirdupois, or approximately 112 Gm., of which the component parts are:

	Per Cent	Gm.
Sodium acetate	90.5	101.4
Glycerin	03.0	3.3
Sodium sulphate crystals	02.0	2.2
Sodium sulphate (anhydrous)	04.5	5.1
	100	112.0

The general shape of the pad is not unlike a tetrahedron, the three sides being made of heavy gage rubber to cut down on the radiation and the fourth side, the base, designed for applying heat directly to the eye, being made of thinner gage rubber, supported by a metal plate. This construction was designed to prevent pressure on the eyeball and so shaped as to rest on the bony rim of the orbit.

Altherm Eye Pad

During the process of manufacture, the heat retaining element is placed within the pad while liquid. After it crystallizes, the orifice through which the element is introduced is permanently sealed by a rubber patch vulcanized over the opening.

The pad is prepared for therapeutic use by placing it in boiling water and boiling it for not more than ten minutes. After this the element will be found to be partially liquefied, and during recrystallization it will give off heat at a comparatively even temperature for approximately forty-five minutes, after which the element will have solidified completely. The temperature will range from approximately 120 down to approximately 110 Fahrenheit. In a clinic acceptable to the Council, these manufacturer's claims were confirmed.

Other tests were made by the firm. After the pad had been boiled from fifteen to twenty minutes and removed from the water, the company found that the temperature would drop rapidly to the point desired for therapeutic use, i.e., 120 F. The company therefore decided to make its instructions read "Boil for ten minutes, not more."

The company points out that the pads cannot be used until boiled, which automatically sterilizes the pads before each application.

The test made by the manufacturer was repeated by the Council. The pad was boiled for ten minutes and temperature readings were made with an ordinary mercury thermometer, the pad being placed on sand. At the beginning of the test the temperature was 127 F. and after thirty minutes it dropped to 110 F. The pad was boiled ten minutes daily for six days,

after which a second series of readings was made. The initial temperature was 120 F and after sixty minutes the temperature had dropped to 118 F. The pad was boiled and used daily for six more days and the second series of readings was recorded. The initial temperature was 116 and after sixty minutes the temperature was 112. The observations of the Council agree quite favorably with those recorded by the manufacturer.

The pad does not fit accurately over the orbital margin of all persons, but dry gauze or cotton can be applied under it to adapt it to various orbits. This method of applying heat seems practical and safe, therefore, the Council places the Altherm Eye Pad on its list of accepted devices.

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

#### CELLU JUICE-PAK YELLOW CLING PEACHES

*Distributor*—The Chicago Dietetic Supply House, Inc., Chicago

*Packer*—Hunt Bros Packing Company, San Francisco

*Description*—Processed, halved, peeled and stoned yellow cling peaches packed in undiluted juice without added sugar.

*Manufacture*—Fully ripened yellow cling stone peaches are halved, pitted, peeled in peeling machines containing hot 1 per cent sodium hydroxide solution, washed with high pressure water sprays to remove peeling and alkali, blanched for one minute in hot water, chilled under pressure sprays, sorted, graded, and placed in cans to which is added undiluted, filtered juice expressed from off-size peaches. The treatment thereafter is essentially the same as for Cellu Juice-Pak Bartlett Pears (THE JOURNAL, Aug 4, 1934, page 341).

Analysis (submitted by distributor) —	per cent
Moisture	90.1
Ash	0.4
Fat (ether extract)	0.2
Protein (N × 6.25)	0.3
Reducing sugars as invert sugar	3.4
Sucrose	3.9
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	8.7

*Calories*—0.4 per gram 11 per ounce

*Claims of Manufacturer*—Packed in undiluted peach juice without added sugar.

- (1) FAUST BRAND CRYSTAL WHITE SYRUP
- (2) FAUST BRAND GOLDEN SYRUP
- (3) INDEX BRAND CRYSTAL WHITE SYRUP
- (4) INDEX BRAND GOLDEN TABLE SYRUP
- (5) MONEY BACK BRAND GOLDEN SYRUP
- (6) RED PLUME BRAND CRYSTAL WHITE TABLE SYRUP
- (7) PLATO CRYSTAL WHITE TABLE SYRUP
- (8) PLATO GOLDEN TABLE SYRUP

*Distributors*—(1) and (2) Sentney Wholesale Grocery Company, Hutchinson Kan (3) and (4) Elliott Grocery Company Logansport, Ind (5) and (6) The C Callahan Company La Fayette, Ind (7) and (8) Union Sales Corporation Columbus, Ind

*Manufacturer*—Union Starch and Refining Company Granite City Ill

*Description*—(1), (3), (6) and (7) Table syrup, corn syrup sweetened with sucrose, flavored with vanilla extract. Same as Silver Drip Brand Crystal White Syrup, THE JOURNAL, June 2, 1934, page 1851.

(2), (4), (5) and (8) Table syrup, corn syrup flavored with refiners' syrup. Same as Golden Drip Brand Golden Table Syrup, THE JOURNAL, May 26, 1934, page 1763.

*Claims of Manufacturer*—For table use and as a carbohydrate supplement for milk modification in infant feeding.

#### CELLU JUICE-PAK ROYAL ANNE CHERRIES

*Distributor*—The Chicago Dietetic Supply House, Inc., Chicago

*Packer*—Eugene Fruit Growers Association, Eugene, Ore.

*Description*—Processed, pitted or unpitted Royal Anne cherries packed in undiluted juice without added sugar.

*Manufacture*—Tree ripened cherries are stemmed under water spray by revolving rolls, graded, water sprayed, sorted according to size and all defective fruit is removed. If not pitted, the fruit is filled into the cans by count. Undiluted juice from off-size cherries is used to fill the cans. The treatment thereafter is essentially the same as for Cellu Juice-Pak Bartlett Pears (THE JOURNAL, Aug 4, 1934, page 341). If pitted, the fruit is boxed, pitted under a water spray, inspected, filled into cans to a standard weight and canned by the same procedure.

*Analysis* (submitted by distributor) —

	(pitted) per cent

Carbohydrates other than crude fiber (by difference)	13.7

*Calories*—0.6 per gram 17 per ounce

*Claims of Manufacturer*—Packed in undiluted cherry juice without added sugar.

#### CALIFORNIA'S PURE PURITAS DRINKING WATER PURE DISTILLED H<sub>2</sub>O

*Distributor*—California Consolidated Water Company, Los Angeles

*Description*—Distilled water practically free of micro organisms.

*Manufacture*—Well water is run through a boiler operated at 175 C. The water vapor is condensed in double brass pipe condensers. The distillate is bottled in cleaned demijohns as described for Arrowhead Soft Spring Water (THE JOURNAL, July 28, 1934, p 261).

*Analysis* (submitted by manufacturer) —

Sanitary Analysis	Parts per million
Turbidity	none
Color	none
Odor	none

Negative tests for metals and acid radicals	

*Micro-Organisms*—Bacterial examination shows the presence of none or very few bacteria per cubic centimeter and no Bacillus coli.

# MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

ANNUAL PRESENTATION OF EDUCATIONAL DATA FOR 1933-1934 BY THE  
COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Notable developments in the teaching of medicine, no less than in other fields of education, have taken place in the decade and a half since the war. In order to evaluate these changes and consolidate the gains that have been made, the Council on Medical Education and Hospitals determined, in the fall of 1933, to undertake a comprehensive resurvey of the medical schools of the United States and Canada. To increase the effectiveness of this study the cooperation of the Association of American Medical Colleges and the Federation of State Medical Boards was secured. In order that the visitation of medical schools might be completed within a reasonably short time, the Council obtained the services of Dr. Herman G. Weiskotten, dean of the School of Medicine of Syracuse University. The general character of the undertaking is a fact-finding study. It is intended to collect and record such information as is pertinent regarding each institution that is included in the survey. Schools that are not now approved will be visited only on request. The necessary data will be secured partly by correspondence and partly from the personal observation and inquiry of the Council's representative. The purpose of the Council and its allied organizations will be achieved in such measure as faculties and administrative officers contribute their own enthusiastic support to the enterprise.

## BLUE PRINT COMMITTEE

While the survey is engaged in finding out what medical education is, the Council is also concerned with what it ought to be. To reappraise the aims and methods of medical teaching, a special committee has been created to act with the Council in the formulation of standards and policies. Its function will be to prepare a plan, or blue print, for the guidance of those who are molding our educational processes. As already announced, its personnel consists of Dr. Reginald Fitz, chairman, Dr. Waller S. Leathers, Dr. Dean Lewis, Dr. Willard C. Rappleye, Dr. Harold Rypins, Rev. Alphonse M. Schwitalla, S. J., and, ex officio, Dr. Ray Lyman Wilbur, chairman of the Council, and Dr. William D. Cutter, secretary.

## PREMEDICAL TRAINING

The minimum standard of premedical education for approved schools of medicine was raised from one year of college work to two years, including courses in physics, chemistry and biology, Jan. 1, 1918. In June 1933, for the sake of uniformity, the following statement from the By-Laws<sup>1</sup> of the Association of American Medical Colleges was adopted by the Council as its own premedical standard. In substance it does not differ from the previous requirement of the Council. The organizations interested in the improvement of medical education do not attempt to outline courses that should be taken in the secondary school.

Sec. 4—Requirements for Admission. Admission to medical schools and medical colleges in membership in the Association may be by

(1) Satisfactory completion of a minimum of collegiate instruction as provided below in Subsection I, or by

(2) Examination as provided in Subsection II.

Subsection I<sup>2</sup> The minimum of collegiate credit required for entrance to medical schools and colleges in membership in the Association shall be not less than two full academic years which shall include English, theoretical and practical courses in physics and biology, and in general and organic chemistry, completed in institutions approved by the accrediting agencies acceptable to the Executive Council of the Association. Exception may be made under this section in that any member may admit applicants who have fulfilled the requirement in American and Canadian institutions not approved by such accrediting agencies, provided that all admissions so made be reported to the Executive Council and shall be published in the next Annual Report of the Council.

All collegiate instruction given in satisfaction of this requirement must be based on the same entrance requirements and

TABLE 1—State Requirements of Premedical Training

must be of the same quality and standard of instruction as that required for a baccalaureate degree in the institution in which the candidate receives his preparation.

Subsection II Admission to medical schools and medical colleges in the Association may be by examination.

Examinations for the purpose of admission by this method shall be conducted by institutions acceptable to the Executive Council of the Association, under the following conditions:

(a) Candidates who have completed two years of collegiate instruction and present evidence of general scholarship of high order, but who lack credits in not more than two of the required subjects, may be admitted on passing examinations in these subjects.

(b) Candidates who have completed three years of collegiate instruction and present evidence of having accomplished work

(Continued on page 570)

<sup>1</sup> Constitution and By-Laws of the Association of American Medical Colleges, amended Nov. 15, 1932.

<sup>2</sup> Since many schools have admission requirements differing from those given in this section, it is important that intending students of medicine at an early date inform themselves as to the exact requirements of that school in which they expect to matriculate.

Note—Action of the Council on Medical Education and Hos-  
pitals, Sept 22, 1933. Resolved, That the University of Mississippi  
School of Medicine be placed on probation until July 1, 1934, and  
that the freshmen enrolled for the session 1933-1934 be recognized  
as three year premedical requirement for the session 1934-1935.  
Enrollment not on above table for classes for the two medical  
schools of the University of Chicago and Duke University.  
Fifth year (Internship) enrollment not included in the total  
column

\* Note—Action of the Council on Medical Education and Hos-  
pitals, Feb 11, 1934. Resolved, That approval of the University  
of Georgia School of Medicine be withdrawn at this time with the  
provision that this decision will not prejudice the transfer of the  
students now enrolled to Class A medical schools at the end of  
the college session.  
Action of the Council, June 16, 1934. Resolved, That in the  
resolution adopted in February 1934 the provision regarding  
transfer of students be amended so as to include those enrolled  
for the session of 1934-1935.

(Continued from page 565)

of distinction in one or more fields of learning, but who lack credit in any or all of the required subjects, may be admitted on passing examinations in these subjects

At the present time, thirty-seven of the seventy-seven approved medical schools in the United States have adopted admission requirements in excess of this minimum, four require a college degree, while three admit students with three years of college work with the stipulation that the baccalaureate be conferred at the end of the first year of medicine. The medical schools of Canada vary with regard to the premedical requirement. Four have a two year requirement, two require one year, one requires three years, and three schools have a six year medical course including pre-medical subjects.

Since 1915 the Council has published annually a list of approved colleges of arts and sciences as a guide to medical schools in the selection of students. This list was a compilation of those colleges approved by the following agencies:

Association of American Universities  
Middle States Association of Colleges and Secondary Schools  
New England Association of Colleges and Secondary Schools  
North Central Association of Colleges and Secondary Schools  
Northwest Association of Secondary and Higher Schools  
Southern Association of Colleges and Secondary Schools

In 1932 this list was discontinued, because the same information was being distributed by the Office of Education in the Department of the Interior at Washington. The data, included in their publications, however, proved to be not readily accessible and the Council has therefore deemed it advisable to resume the publication of its own list. A new edition will be available in October. The Association of American Medical Colleges endorses the lists of evaluating agencies included in the Council's publication but in addition recognizes also the colleges approved by a state university. The constitution of the Association of American Medical Colleges provides that any medical school may accept a student coming from an unapproved arts college but requires that it send a record of that fact to the office of the Association. The Council approves of this arrangement. Prospective medical students do well, however, to secure their premedical training in colleges that are included in the Council's publications. Otherwise they may find it difficult or impossible to enter the medical school of their choice, for, while there is no inviolable rule excluding applicants from unaccredited colleges, officials, in selecting from so large a number, give the preference to those whose preparation has been received in institutions that are known to conform to accepted standards. Many schools will not admit a student from an unaccredited college. In 1931 the Association of American Medical Colleges passed a resolution recommending the use of aptitude tests as an additional guide in the selection of students. These tests include (1) comprehension and retention, (2) visual memory, (3) memory for content, (4) logical reasoning, (5) scientific vocabulary, (6) ability to follow directions and (7) understanding of printed material. This recommendation likewise meets with the approval of the Council. Accordingly, the majority of schools in the selection of students employ the test scores along with college grades, letters from instructors and personal interviews. The aptitude test in the fall

of 1933 was administered to 9,398 students in 546 colleges. The results of the test are made available to admitting officers in February.

While the premedical requirement of this Council and the College Association is two years, statistics compiled by the latter organization indicated that, in 1932, 28.6 per cent presented an A B degree for entrance, 20.5 per cent a B S degree, 26.6 per cent three and three plus years, 16.5 per cent two and two plus years, 4.1 per cent four years or more, and 3.4 per cent were listed under "others." The preliminary requirements of the individual schools will be found in table 2.

No attempt has been made to outline the admission requirements of the approved schools, since they vary considerably. It is essential that each applicant secure from the school he desires to enter an official statement of its requirements.

Although, for sixteen years, two years of premedical college training has been required by every approved medical school, there are still nine states that have failed to adopt this standard as a legal requirement. However, these states do not admit to licensure other than graduates of recognized medical schools, all of which have a requirement of at least two years of college work. These states should take measures to amend their laws to conform with universally accepted standards. Statutory requirements are shown in table 1 with the dates at which each became effective.

#### ACKNOWLEDGMENT

Statistics are presented herewith based on official reports from the approved, or class A, medical schools of the United States and Canada, from the medical schools of other countries, and from the thirteenth edition of the American Medical Directory. There are also included lists of hospitals approved for intern training and residencies by the Council based on reports received directly from the institutions, and a list of institutions offering graduate courses for physicians. Acknowledgment is here given for the prompt response and the kind cooperation of the officers of the schools and hospitals who have made the presentation of these statistics possible.

#### LENGTH OF MEDICAL COURSE

The medical course in the United States in general covers four calendar years. A few schools, namely, the medical schools of the University of Minnesota, Duke and Tennessee, operate on the quarter system permitting the student by utilizing the summer months to decrease the length of time necessary to obtain his degree. The two medical schools of the University of Chicago also operate on the quarter system but in addition have instituted the individualized plan of instruction whereby a student progresses as rapidly as his ability permits. Fourteen medical schools require a year of internship or research as a part of the medical course, thereby lengthening the course to five years. Duke University requires a two year internship. Ten schools offer only the work of the first two years. Five of the medical schools of Canada offer a five year course, including one, two or three years of premedical studies, three have a six year course with two years of premedical studies, one a four year course with two years of premedical education, and the University of Saskatchewan has a two year premedical requirement and offers only the first two years of the medical course. These data are included in table 2.

## CURRICULUM

The Council recognizes as the standard curriculum that provided in the By-Laws<sup>1</sup> of the Association of American Medical Colleges, which is as follows:

Sec 5 Curriculum. The entire course of four years shall consist of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours per year, and shall be grouped as set forth in the following schedule, each group to be allotted approximately the percentage of hours of the whole number of hours in the courses as stated:

	Hours	Per Cent
1 Anatomy including embryology and histology	14	18.5
2 Physiology	4.5	6
3 Biochemistry	3.5	4.5
4 Pathology bacteriology and immunology	10	13
5 Pharmacology	4	5
6 Hygiene and sanitation	3	4
7 General medicine	20	26.5
Neurology and psychiatry		
Pediatrics		
Dermatology and syphilis		
8 General surgery	13	17.5
Orthopedic surgery		
Urology		
Ophthalmology		
Otolaryngology		
Röntgenology		
9 Obstetrics and gynecology	4	5
Total	76	100
Electives	24	0

When the teaching conditions demand it, a subject may be transferred from one division to another.

## STATISTICS OF MEDICAL SCHOOLS

Table 2, pages 566 and 567, lists the approved medical schools that were in session during 1933-1934 and contains data regarding the premedical requirement, length of course, enrolment by classes, graduates, dates of the beginning and ending of the forthcoming session, the name of the executive officer and the month until when applications for admission to the freshman class are received. Changes in the classifications that have taken place since the publication of the educational statistics in 1933<sup>3</sup> can be noted in the footnotes at the bottom of the table. Also contained in the footnotes are references to those institutions which have raised their premedical requirement for the coming session and those which admit students at varying times during the year. The data here presented constitute the basis also for several of the subsequent tabulations. Beginning on page 580 are given the essential facts concerning all approved medical colleges arranged by states.

This table differs slightly from that published in previous years. No tabulation has been made of the tuition fees or of the graduates with baccalaureate degrees, nor is there included the population of the cities wherein medical schools are located.

The figures indicate that there were 6,457 freshman students enrolled, 5,571 sophomores, 4,988 juniors and 4,937 seniors, during the session just ended. The students enrolled in the two medical schools of the University of Chicago and Duke University are not classified by years. In these three schools there were 846 students enrolled, a total of 22,799 students in the seventy-seven approved medical schools in the United States. This figure is exclusive of Canada, wherein there were 2,742 students enrolled as follows: first year, 622, second year, 595, third year, 529, fourth year, 500, fifth year, 320, and sixth year, 176. Altogether, 25,541 students were studying medicine, exclusive of those interning as a requirement for the degree, during the session just closed, of which 5,038 graduated from American schools and 476 from nine Canadian schools. There were enrolled seventy-five part time, 249 special and 787 graduate students.

## HOME STATES OF STUDENTS

Table 3, pages 568 and 569, shows from what states the students came who were in attendance at each medical school during the past session. The states having medical colleges contributed larger numbers of students than those which have no medical colleges. The state furnishing the greatest number of students this year was New York, 3,413, followed by Pennsylvania with 2,162, Illinois with 1,548, and Ohio with 1,346. Of the twelve states that do not have medical schools, five furnished more than 100 students, these being New Jersey, 943, Washington, 211, Rhode Island, 165, Florida, 134, and Maine, 124. Of the noncollege states, Montana had 65, Idaho 48, Delaware 43, Arizona 42, New Mexico 31, Nevada 16 and Wyoming 14. There were 108 students who came from the government possessions and 2,690 from foreign countries. The greater portion of this number, however, were Canadians enrolled in the medical schools of Canada.

## SCHOOLS, STUDENTS AND GRADUATES BY STATES

The number of schools, students and graduates for each state are given in table 4. New York, with nine schools, the largest number, naturally had the largest number of students and graduates, 2,739 and 627, respectively. Pennsylvania, with six schools, was second with 2,403 students and 573 graduates. Illinois, with five schools, had 2,301 students and 537 graduates, and

TABLE 4—Schools, Students and Graduates by States

State	Schools	Students	Graduates
Alabama	1	124	
Arkansas	1	200	50
California	4	1,013	215
Colorado	1	206	51
Connecticut	1	209	40
District of Columbia	3	1,045	271
Georgia	2	378	89
Illinois	5	2,301	537
Indiana	1	465	116
Iowa	1	3-3	72
Kansas	1	300	68
Kentucky	1	348	94
Louisiana	2	706	101
Maryland	2	728	176
Massachusetts	3	1,230	236
Michigan	2	775	164
Minnesota	1	614	114
Mississippi	1	61	
Missouri	3	941	109
Nebraska	2	638	154
New Hampshire	1	41	
New York	9	2,739	627
North Carolina	3	321	33
North Dakota	1	69	
Ohio	3	946	212
Oklahoma	1	243	61
Oregon	1	230	56
Pennsylvania	6	2,403	573
South Carolina	1	159	31
South Dakota	1	57	
Tennessee	3	784	174
Texas	2	710	134
Utah	1	70	
Vermont	1	170	33
Virginia	2	575	140
West Virginia	1	138	
Wisconsin	2	619	102
Totals	77	22,799	5,038

California, with four schools, had 1,013 students and 215 graduates. The District of Columbia and Massachusetts, each with three schools, had more students and graduates than California. Included among the number of students are the figures for ten institutions that offer only the preclinical courses.

## REQUIRED INTERNSHIPS

Tables 5 and 6 show the state licensing boards and medical schools now requiring internships for licensure and the M.D. degree respectively. There is also

included the effective date of the requirement. The requirement became effective in Vermont during the current year and also at Louisiana State University Medical Center. While some of the boards may have

## MEDICAL EDUCATION

573

VOLUME 103  
NUMBER 8

which was in July of this year. There are 1,183 students of the United States and 154 of Canada serving internships as a requirement for the degree, a total of 1,337, included in this table. The figure for

where list only those graduated since July 1, 1933. The second column, however, includes those serving internships as a requirement for the degree. With the exception of one in Canada, every school in the list has more than 90 per cent of its graduates serving internships, and in twenty-three schools 100 per cent interned. Excluding those schools that require the internship for graduation, 94 per cent of all graduates here listed have this added experience. It is a known fact that there is a scarcity of internships and it may be that of the 6 per cent who have not been reported as interning many have found it difficult to secure internships in approved hospitals.

## DISTRIBUTION BY SEX

Students and graduates classified by sex are shown in table 9. There were seventy-five schools which had both men and women students in the United States and Canada, of which sixty had women graduates. Altogether there were 24,402 men and 1,139 women students, and 5,284 men and 230 women graduates. There is one medical college for women, the Woman's Medical College of Pennsylvania, which had 122 students and 19 graduates, leaving 1,017 women students pursuing their medical education and 211 who completed the course in coeducational institutions.

TABLE 10—Women in Medicine in the United States

Year	Women Students	Percentage of All Students	Women Graduates	Percentage of All Graduates
1905	1,078	4.1	210	4.0
1910	907	4.0	110	2.6
1915	592	4.0	92	2.6
1920	818	5.8	122	4.0
1925	910	5.0	204	5.1
1926	935	5.0	212	5.4
1927	904	4.9	189	4.7
1928	929	4.5	207	4.9
1929	925	4.4	214	4.8
1930	955	4.4	204	4.5
1931	990	4.5	217	4.6
1932	955	4.3	208	4.2
1933	1,017	4.7	214	4.4
1934	1,020	4.5	211	4.2

During the past year there were 1,020 women studying medicine in the United States, 36 more than last year. The percentage of women to all medical students this year is 4.5 as compared with 4.7 in 1933. There were 211 graduates, three fewer than last year. Of all the women matriculants, 122 students were in attendance at the one medical college for women, the Woman's Medical College of Pennsylvania, while 898 were matriculated in 67 coeducational schools. From the Woman's Medical College, 19 were graduated while 192 secured their degrees from coeducational institutions. As shown in table 10, the number of women students has been quite constant since 1920, although there has been an increase in the four years preceding 1934.

MEDICAL SCHOOLS STUDENTS AND GRADUATES IN  
THE UNITED STATES 1905-1934

The number of medical schools students and graduates in the United States for each five year period from 1905 to 1920, and for each year since, is shown in table 11. The total number of undergraduate medical students for the college session 1933-1934 was 22,799, an increase of 333 over the previous session. This is the largest number of students enrolled since 1905, when 26,147 were in attendance at the 160 medical schools then existing. Also included are figures covering the number of students enrolled in schools offering only the preclinical courses. Not included in the total number of students for 1934 are 75 part time, 249

the graduates differs from that mentioned elsewhere in these statistics because those interning as a requirement for the degree are omitted and all graduates of the year 1933 are included, while the statistics else-

special and 787 graduate students majoring in the medical school but not working for M D degrees

The largest number of medical colleges existed in 1906, when there were 162

Again referring to table 11, it will be noted that the total number of graduates was 5,038, an increase of 143 over the preceding session With the exception of the slight decrease in the number of graduates in 1933, as compared with previous years, there has been a gradual increase since 1925, which is shown graphically in the chart As will be noted, there were noticeable increases in 1924 and 1925 While there was a decrease in the number of graduates in 1933, there was an increase in the number of students

In this connection it is interesting to note the number enrolled in the various classes in the United States for each session from 1929-1930 to 1933-1934 inclusive,

Increase of medical graduates in the United States

as shown in table 12 The total attendance for the first year for the session 1933-1934 was 6,457, or 31 more than the number enrolled for the session 1932-1933 The figure, however, is 197 more than were enrolled during 1931-1932 The total attendance for the remainder of the classes was, respectively, 5,571, 4,988 and 4,937 The two medical schools of the University of Chicago are not operated under the promotion by class system but on an individual plan It is not possible, therefore to group them into the figures given This is likewise true of the enrolment at Duke University School of Medicine They are, however, included in the totals There were 193 students enrolled at Duke, 325 at the School of Medicine of the Biological Sciences of the University of Chicago and 328 at Rush Medical College, a total of 846 There were 1,202 more students enrolled than in 1929-1930 Only one new medical school has opened since that session, namely,

the Louisiana State University Medical Center, which had an enrolment of 210 for the session of 1933-1934 Excluding the students of this university, there were 992 more students enrolled during the past college session in the seventy-six medical schools that existed in 1930

The Association of American Medical Colleges<sup>4</sup> reports that there were 29,940 (includes figures from several Canadian schools) applications for admission

TABLE 11—Schools, Students and Graduates in the United States

year Meharry Medical College was organized in 1876 as a medical college for Negro youth, and at Howard University College of Medicine, organized in 1869, they compose a majority of those in attendance These two schools graduated the majority of the Negro students All other schools enrolled less than five

TUITION AND OTHER FEES

In table 14, the eighty-seven medical colleges of the United States and Canada have been grouped according to the amount of fees charged To arrive at the figures listed, an average was compiled of the fees for each

school Three colleges have fees of less than \$100 a year These were the State University of Louisiana, North Dakota and Oklahoma They, however, charge an additional fee of \$300, \$90 and \$200, respectively, for nonresidents The eleven colleges having fees over \$500 are Yale, George Washington, Johns Hopkins, Columbia, Cornell, Long Island, New York Homeopathic, Syracuse, University and Bellevue, Buffalo and Pennsylvania There were thirty-two universities which made an additional charge for nonresidents, ranging from \$50 by the Universities of Mississippi, Missouri, Cincinnati (nonresidents of Cincinnati), Tennessee and Virginia to \$300 exacted by the Universities of California and Louisiana State The lowest nonresident fee was charged by the University of Oregon, \$20, followed by the University of Utah, \$35, and the University of Vermont, \$45 (\$20 for the senior year) All other schools had a nonresident fee of \$50 or more The fees are not listed in these statistics by individual schools other than in the descriptions beginning on page 580 Though the total annual fees in some instances seem somewhat large, they do not by any means cover the cost of the instruction that is given No medical school at the present time can maintain extensive laboratories, pay the essential salaries to teachers and properly teach modern medicine without an income larger than that derived from students' fees Medical schools, along with other institutions of higher learning, have been affected by the

Forty-six medical schools report that they have funds available for scholarships and fifty-seven have loan funds The students who received assistance by either of these methods during the last college session number 2,373

The Federal Emergency Relief Administration has adopted a plan of part time employment of college students during the college year 1934-1935 Students may be assigned to extension, adult education, recreation and other activities that increase the usefulness of the college to the community, in addition to clerical, library and research work The salary earned shall be

CITIZENS OF THE UNITED STATES REPORTED  
ENROLLED IN MEDICAL FACULTIES ABROAD

In 1931, in view of the reported exodus of citizens of the United States to foreign medical schools, inquiries were sent to all schools This study has been carried on since and the results for the year 1933-1934 are shown in table 15 There were 1,428 American students and 86 graduates in the eighty-four institutions reporting

In February 1933, the Federation of State Medical Boards adopted the following resolution

1 That no American student matriculating in a European medical school subsequent to the academic year 1932-1933 will be admitted to any state medical licensing examination who does not, before beginning such medical study, secure from a state board of medical examiners or other competent state authority a certificate endorsed by the Association of American Medical Colleges or the Council on Medical Education and Hospitals of the American Medical Association showing that he has met the premedical educational requirements prescribed by the aforementioned associations

2 That no student either American or European matriculating in a European medical school subsequent to the academic year 1932-1933 will be admitted to any state medical licensing examination who does not present satisfactory evidence of premedical education equivalent to the requirements of the Association of American Medical Colleges, and the Council on Medical Education and Hospitals of the American Medical Association, and graduation from a European medical school after a medical course of at least four academic years, and submit evidence of having satisfactorily passed the examination to obtain a license to practice medicine in the country in which the medical school from which he is graduated is located

This policy of the federation has been translated into action by some of the states For the purpose of keeping closely in touch with developments in other countries, a joint committee was appointed representing

economic situation Almost without exception income has been reduced and, in order to balance the budget, fees have been increased In addition to student fees, many of the schools received donations from various sources throughout the session such as gifts, bequests and endowments, as well as their usual appropriations from state and private enterprises Provision, however, has been made for scholarships and loan funds for the benefit of deserving students

the Council on Medical Education and Hospitals of the American Medical Association, the Federation of State Medical Boards of the United States, the New York Board of Regents, the National Board of Medical Examiners, and the Association of American Medical Colleges

The governments of many European countries have already taken cognizance of the situation and sent representatives to this country to discuss appropriate measures for dealing with students from the United States. In some universities, entrance requirements have been raised, in some, student enrolment has been

the maintenance of high educational and professional standards, physicians who are victims of racial and religious persecution in Germany be permitted the privilege of practicing medicine in the United States

2 That the voluntary method of selecting in this country students for admission to Italian medical schools serve as a model for similar agreements with other European countries and that a committee be appointed to advise and assist European authorities in reference to the selection of American students

3 That the committee be continued with authority to carry on further negotiations with the various European authorities looking toward a proper selection and restriction of American students in Europe

\* It is believed this figure should be larger inasmuch as the following schools reported large numbers of American students in 1933 and have not replied to the 1934 request: Vienna Austria, Karlovy, Prague Czechoslovakia, Hamburg and Königsburg Germany, Bologna and Naples, Italy.

limited. In all cases, credentials will be carefully scrutinized.

The Committee on Foreign Medical Students published its report<sup>5</sup> in November 1933, which was adopted by the Federation in February 1934 and reported its adoption by all its constituent licensing boards. Its recommendations were as follows:

1 That no action be taken in reference to the admission of native-born Europeans for admission to American medical licensing examinations and that, so far as is consistent with

In further considering the problem, the federation at its February 1934 meeting passed the following resolution in order that an influx of American students to countries other than Europe might be curtailed if possible:

WHEREAS It has been brought to the attention of the Federation of State Medical Boards of the United States that an unknown number of American students are studying medicine in foreign medical schools where adequate information concerning standards of medical education is not available therefore be it

Resolved That the Federation of State Medical Boards of the United States recommend to its constituent state boards and to the National Board of Medical Examiners that until adequate information is available

able these boards deny graduates of foreign medical schools admission to the various medical licensure examinations, and be it further

*Resolved* That a copy of these resolutions be transmitted to the Council on Medical Education and Hospitals of the American Medical Association and to the Association of American Medical Colleges with the request that full and adequate publicity be given to this resolution

It is believed that a better understanding has been achieved and a noticeable decrease is indicated in the number at present enrolled and it is believed that the figure will steadily decrease

\* See footnote to table 15

The number of students studying in the various countries during the four years in which the study has been carried on is indicated in table 16. It can readily be seen that the largest numbers were enrolled in Germany, Scotland, Switzerland and Italy. While in the beginning Scotland had the greatest number, this country was one of the first to curtail admission of such students. Thereafter, large numbers enrolled in Germany and Italy and lastly in Switzerland. There were, however, fewer admitted to the study of medicine in all European countries in 1933-1934 than formerly. The figures given represent largely those previously enrolled.

With the cooperation of the State Department at Washington, an investigation is being made of medical education and licensure in Latin America. The information that is being obtained includes name and location of all existing professional schools with the year in which they were organized, preliminary training required for admission, requirements for degree of Doctor of Medicine, including length of course, subjects of the curriculum, time devoted to individual laboratory work, size and character of teaching hospitals, number of students enrolled and requirements for practice by citizens of the United States.

#### HOSPITAL FACILITIES

Fifty-seven of the eighty-seven medical schools of the United States and Canada report that they maintain their own hospital or outpatient clinic, five report they have hospital affiliations and, seventeen that they do not

maintain their own hospital or clinic, while eight did not answer.

Fifty-eight replied that indigent patients are accepted, one stated they are not and the remainder did not reply. In forty-nine, patients are accepted who are able to pay a part of the cost of their care, seven replied that they are not able, and the remainder did not comment. Thirty-four accept patients able to pay the full cost of their care, including a physicians' fee, nineteen do not, and others did not report.

#### RATIO OF PHYSICIANS TO POPULATION

The ratio of physicians to population in the United States based on physicians listed in the thirteenth edition of the American Medical Directory, which has just been issued, and the estimated census of July 1, 1933, is shown in table 17. These figures have been

TABLE 17—*Ratio of Physicians to Population in the United States*

\* No estimate available

† Excluding those listed as retired or not in practice

corrected by the omission of 6 866 names listed as "retired" or "not in practice." Hence the ratios given represent, it is believed, the nearest approximation that can be made to the number of physicians actually engaged in practice. In the entire country the ratio is one physician to 814 people. In seventeen states the ratio is over 1,000 and in practically all others it ranges above 500. The lowest ratio is that for the District of Columbia (290), but this is accounted for by the fact that many physicians are in the government service.

New York is next with 585, while in Colorado the ratio is 598 The state having the highest ratio is Mississippi, 1,411

AMERICAN MEDICAL DIRECTORY

The number of physicians listed in the 1931 and 1934 editions of the American Medical Directory, indicating whether the medical profession has been added to or

\* Including those listed as retired and not in practice

decreased, is included in table 18 The state showing the largest gain was New York with 1,808, 7 9 per cent In New York 1,118 of those listed in 1931 were removed by death, 3,062 were new additions to the profession and 1,026 moved to New York from other states, while 1,162 residents of New York left the state, leaving a gain of 1,808 The greatest loss was in Arkansas, eighty-seven, or 4 4 per cent For this state it might be noted that 191 were removed by death, 124 were new physicians and 80 moved to Arkansas from other states, while 100 left the state

For the entire country there was a gain of 4,955, or 3 1 per cent In this table no correction has been made for those retired or not in practice

At the bottom of the table the states are divided into geographic divisions All divisions but the East South Central showed a gain, the most noticeable being in the Middle Atlantic, 7 2 per cent, and the New England, 5 7 per cent, groups The lowest gain was in the West North Central division, 0 1 per cent, while the loss in the East South Central group was 1 8 per cent

PHYSICIANS AND SPECIALTIES

In table 19 are recorded figures showing the number of physicians who have reported that they limit their practice or declare an interest in a specialty This

Psychiatry	506	216	722
Totals	26 756	23 577	50 333

information forms a part of their biographic record in the thirteenth edition of the American Medical Directory Twenty-four specialties are included and are listed alphabetically with the exception of the three groups given at the end of the list, each of which includes two or more closely related specialties The largest number limiting their practice to a specialty is found in internal medicine, 4,452, followed by surgery with 4,337 and ophthalmology, otology, laryngology and rhinology with 4,010 The smallest number limiting their practice are the bacteriologists, 34 A total of 26,756 indicate that they limit their practice to a specialty

Of the 23,577 who declare a special interest in a specialty, the largest group is represented by surgery, 8,854, followed by pediatrics, 2,155, obstetrics, 2,001,

obstetrics and gynecology, 1,774, and gynecology, 1,032. In other fields the number does not exceed 1,000.

Altogether, 50,333 of the 161,361 physicians listed in the United States, or 154,495 eliminating the 6,866 reported as retired or not in practice, 32.6 per cent, report that they limit their practice or declare a special interest in a specialty. Those who limit their practice constitute 17.3 per cent, and those who declare a special interest, 15.3 per cent of the profession.

The House of Delegates of the American Medical Association at its annual session in 1933 passed the following resolution:

*Resolved* That the Council on Medical Education and Hospitals is hereby authorized to express its approval of such examining boards in medical specialties as conform to the standards of administration formulated by the Council and be it further

*Resolved* That the Board of Trustees of the American Medical Association be urged to use the machinery of the American Medical Association including the publication of its directory in furthering the work of such examining boards as may be accredited by the Council.

The following Essentials for Examining Boards in Specialties were approved by the House of Delegates at its 1934 session:

## ESSENTIALS FOR EXAMINING BOARDS IN SPECIALTIES

By THE COUNCIL ON MEDICAL EDUCATION AND  
HOSPITALS OF THE AMERICAN MEDICAL  
ASSOCIATION, CHICAGO

### I ORGANIZATION

1 A special examining board to be approved by the Council should represent a well recognized and distinct specialty of medicine.

2 It should be composed of representatives of the national organizations of that specialty including the related section of the American Medical Association.

3 It should be incorporated.

4 A special board should:

- Determine whether candidates have received adequate preparation as defined by the board.
- Provide a comprehensive test of the ability and fitness of such candidates.
- Certify to the competence of those physicians who have satisfied the requirements of the board.

### II DEFINITION OF SPECIAL FIELDS

The following branches of medicine at present are recognized as suitable fields for the certification of specialists:

- |                             |                               |
|-----------------------------|-------------------------------|
| 1 Internal medicine         | 7 Dermatology and syphilology |
| 2 Surgery                   | 8 Neurology and psychiatry    |
| 3 Pediatrics                | 9 Urology                     |
| 4 Obstetrics and gynecology | 10 Orthopedic surgery         |
| 5 Ophthalmology             | 11 Radiology                  |
| 6 Otolaryngology            | 12 Pathology                  |

### III QUALIFICATION OF CANDIDATES

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

#### A General Qualifications<sup>1</sup>

- Satisfactory moral and ethical standing in the profession.
- A license to practice medicine.
- Membership in the American Medical Association or by courtesy membership in such Canadian medical societies as are approved by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies should not be required.

#### B Professional Education<sup>1</sup>

- Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
- Completion of an internship of not less than one year in a hospital approved by the same Council.

#### C Special Training<sup>1</sup> (to be effective not later than Jan 1, 1938)

- A period of study after the internship of not less than three calendar years in clinics, dispensaries, hospitals or laboratories recognized by the same Council as competent to provide a satisfactory training in the special field of study.
- This period of specialized preparation shall include:
  - intensive graduate training in anatomy, physiology, pathology and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty in question,
  - an active experience of not less than eighteen months in hospitals, clinics, dispensaries or diagnostic laboratories recognized by the Council as competent in the specialty,
  - examinations in the basic medical sciences of a specialty as well as in the medical laboratory and public health aspects.
- An additional period of not less than two years of practice.

### IV WITHDRAWAL

For reasons which are deemed sufficient, in the judgment of the Council on Medical Education and Hospitals, the recognition extended by the American Medical Association to holders of certificates from special examining boards may be withdrawn.

### INTERNSHIPS AND RESIDENCIES

This issue of the Educational Number presents in a new form lists of hospitals approved for the training of interns and residents. The Council desires to make available to candidates for these positions more comprehensive and pertinent information. The data for the most part were obtained from the regular annual reports from all hospitals approved by the Council, supplemented by inspection reports and personal knowledge of the staff.

Under the heading "Classification of Patients," the data given will enable the prospective intern to know whether an institution serves predominantly private or charity patients.

TABLE 20—Approved Internship Hospitals

	Beds and Bassineets	Admissions	Interns
Fifty teaching hospitals	30,671	511,237	1,221
Fifty government hospitals	29,903	410,047	968
Fifty church hospitals	13,105	190,648	266
Fifty independent hospitals	12,780	218,930	392
Teaching hospitals: one intern to 25 beds to 418 admissions			
Government hospitals: one intern to 33 beds, to 402 admissions			
Church hospitals: one intern to 49 beds to 716 admissions			
Independent hospitals: one intern to 33 beds to 553 admissions			

Additional information is presented also in the column headed "Type of Internship," for it is recognized that desirable internships do not all necessarily follow the same pattern.

A "straight service" is one in which the intern spends his entire time in one clinical department.

A "rotating service" includes experience in each of the following branches: medicine, surgery, obstetrics, pediatrics, radiology and pathology. This type of service usually satisfies those state boards which have an intern requirement.

The "mixed internship," intermediate between the other two, offers training in more than one, but less than six, of the fields comprised in the full rotating service. A mixed internship may often be supplemented by special training in one or two fields in order to fulfill state board requirements.

Formerly the Council expressed the opinion that a hospital should employ interns in the ratio of one to each thirty beds. It has become evident however that, owing to fluctuations in the percentage of occupancy,

<sup>1</sup> In case of an applicant whose training has been received outside the United States and Canada the credentials must be satisfactory to the Advisory Board.

this standard is not entirely satisfactory. It has been suggested that there should be a definite ratio of interns to the number of patients shown in the average daily

TABLE 21—Approved Internship Hospitals with Highest Necropsy Percentages, 1933

	Control	Deaths	Necropsies	Necropsy Percentage
1 St. Luke's Hospital Kansas City Mo	Church	121	105	86.8

20 Grasslands Hospital, Valhalla, N Y	County	439	296	67.4

Indep—Independent Fed—Federal Indus—Industrial

census. This proposal has the weakness that some hospitals have a very slow turnover, and that the interns' experience would therefore be less satisfactory

than the census would indicate. The Council has therefore made a brief analysis of the ratio of interns to admissions in four types of institutions, each group being represented by a sample of fifty hospitals. The results are given in table 20.

Experience shows that hospitals employing fewer than four interns have difficulty in providing a well balanced service. There is a tendency to overemphasis on surgery, especially operations and routine history writing, with inadequate attention to physical examination and diagnosis. With few exceptions this type of service is undesirable.

The publication of figures showing the percentage of necropsies performed should be most helpful to prospective interns, for it is well known that an alert and efficient staff will maintain a creditable postmortem rate. Failure to satisfy the Council's requirement will necessarily lead to suspension from the approved list.

There is included a list of the twenty approved internship hospitals most successful in necropsy performance during 1933. Attention is called not only to the excellence of the figures but also to the fact that nearly every kind of hospital according to type of control is included. In the governmentally controlled group there are representatives of federal, state, county and city hospitals, in the voluntary group are to be found Jewish, Catholic, Protestant, independent and industrial hospitals. There is also the widest possible geographic distribution. The conclusion seems justified that any kind of hospital can readily exceed the minimum requirements if the staff is sufficiently interested in procuring necropsies.

## DESCRIPTION OF MEDICAL COLLEGES

### ALABAMA

#### University

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1863 inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907 when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. Coeducational since 1920. Minimum entrance requirements are seventy semester hours of collegiate work. The course of study covers two years of thirty-six weeks each. The faculty includes 23 professors and 10 instructors, assistants, etc. a total of 23. The tuition fees are \$271 each year. Total registration for 1933-1934 was 124. The sixty-ninth session begins Sept. 12, 1934 and ends May 28, 1935. The Dean is Stuart Graves, M.D.

### ARKANSAS

#### Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE 300 West Markham Street—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 35 professors and 55 lecturers and assistants total 90. The curriculum covers four years of nine months each. Entrance requirements are two years of collegiate work in addition to a four-year high school course. The fees for the four years respectively for residents of Arkansas are \$200 \$200 \$200 and \$200 nonresidents are charged \$150 additional each year. The total registration for 1933-1934 was 200 graduates 50. The fifty-sixth session begins Sept. 19, 1934 and ends June 3, 1935. The Dean is Frank Vinsonbaler, M.D.

### CALIFORNIA

#### Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL University Campus, Berkeley Third and Parnassus avenues San Francisco—Organized in 1862 as the Toland Medical College. The first class graduated in 1864. In 1872 it became the Medical Department of the University of California. In 1909 by legislative enactment the College of Medicine of the University of Southern California at Los Angeles became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged and elective chairs in homeopathic materia medica and therapeutics were provided.

Coeducational since organization. Three years of collegiate work is required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The faculty is composed of 132 professors and 225 associates and assistants, a total of 357. The course covers four years of eight months each and an additional fifth year consisting of an internship in a hospital or of special work in a department of the medical school. Fees for the four years respectively for residents of California are \$277, \$235, \$235 and \$235 nonresidents are charged \$300 additional each year. Total registration for 1933-1934 was 226 graduates, 56. The sixty-second session begins Aug. 20, 1934 and ends May 18, 1935. The Dean is Langley Porter, M.D., San Francisco.

#### Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda the clinical departments at Los Angeles. Coeducational since organization. The faculty is composed of 58 professors and 196 associates, assistants and instructors a total of 254. The course covers a period of five years including one year of internship. During the first and second years the students are in school twelve months each year. This is accomplished by means of the cooperative plan, the student spending alternate months in an approved hospital in practical lines of medical training. Sixty-four semester hours of collegiate work is required for admission. The total fees for the four years respectively are \$385, \$375, \$480 and \$440. The total registration for 1933-1934 was 406 graduates 88. The twenty-sixth session begins July 2, 1934 and ends June 16, 1935. The Dean of the Loma Linda Division is E. H. Risley, M.D., and the Dean of the Los Angeles Division is Arthur E. Coyne, M.D.

#### Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE 3551 University Avenue—Organized in 1885 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Medical Department of the University of California in Los Angeles. In 1909 the College of Physicians and Surgeons established in 1904 became the Medical Department of the University of Southern California. Its activities were suspended in 1920, reorganized in May 1928 under present title. The faculty consists of 129 professors and 113 instructors assistants and others a total of 242. A fifth intern year is required. Three years of collegiate work is required for admission. Coeducational since organization. Annual fees amount to \$450. The total registration for 1933-1934 was 171 graduates, 30. The next session begins Sept. 24, 1934 and ends June 12, 1935. The Dean is Paul S. McKibben, Ph.D.

#### San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE 2398 Sacramento Street San Francisco—Organized in 1908 when by agreement the interests of Cooper Medical College were taken over. The first class was graduated in

1913 Coeducational since organization The faculty consists of 107 professors and 142 lecturers assistants and others a total of 249 Three years of collegiate work is required for admission The course covers four years of eight and one half months each, plus a fifth year of intern work The fees for the four years respectively, are \$467 \$444, \$361 and \$361 The total registration for 1933 1934 was 210 graduates, 41 The twenty fifth session begins Oct 2 1934, and ends June 12, 1935 The Dean is Loren Roscoe Chandler, M D

## COLORADO

### Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE 4200 East Ninth Avenue—Organized in 1883 Classes were graduated in 1885 and in all subsequent years except 1898 and 1899 Denver and Gross College of Medicine was merged Jan 1, 1911 Coeducational since organization The faculty is composed of 57 professors and 130 lecturers instructors and assistants, a total of 187 The course covers four years of nine months each The entrance requirements are three years of collegiate work The fees for residents of Colorado for each of the four years are respectively, \$211 \$231 \$181 and \$191 Nonresidents are charged \$132 additional each year The total registration for 1933 1934 was 206 graduates, 51 The fifty third session begins Sept 24, 1934 and ends June 10 1935 The Dean is Maurice H Rees M D

## CONNECTICUT

### New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE 333 Cedar Street—Chartered in 1810 as the Medical Institution of Yale College Organized in 1812, instruction began in 1813 first class graduated in 1814 A new charter in 1879 changed the name to the Medical Department of Yale College In 1884 the Connecticut Medical Society surrendered such authority as had been granted by the first charter In 1887 Yale College became Yale University Coeducational since 1916 The faculty consists of 108 professors and 174 lecturers and assistants a total of 282 The requirements for admission are three years of collegiate work plus completion of courses in physics, inorganic chemistry qualitative analysis general biology, organic chemistry and physical chemistry or laboratory physics all equivalent to the courses in these subjects in Yale University The student also must have two years of French or German The course covers four years of nine months each The fees for the four years, respectively are \$505 \$500 \$500 and \$520 The total registration for 1933 1934 was 209 graduates 40 The one hundred and twenty second session begins Sept 24 1934, and ends June 12, 1935 The Dean is Milton C Winternitz M D

## DISTRICT OF COLUMBIA

### Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE 3900 Reservoir Road NW—Organized 1851 First class graduated in 1852 The faculty is composed of 50 professors, 165 instructors and assistants total 215 Three years of collegiate work is required for entrance The course of study covers four terms of eight and one half months each The present fees for each of the four sessions respectively are \$465 \$460 \$410 and \$410 The total registration for 1933 1934 was 546 graduates 154 The eighty fourth session begins Sept 10 1934 and ends June 10 1935 The Dean is William Gerry Morgan, M D

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE 1335 H Street NW—Organized in 1825 as the Medical Department of Columbian College Also authorized to use the name National Medical College Classes were graduated in 1826 and in all subsequent years except 1844 to 1838 and 1861 to 1863 inclusive The original title was changed to Medical Department of Columbian University in 1873 In 1903 it absorbed the National University Medical Department In 1904 by an act of Congress the title of George Washington University was granted to the institution Coeducational since 1884 The faculty is composed of 50 professors and 108 instructors demonstrators and assistants a total of 158 Two years of collegiate work is required for admission The course covers four years of thirty two weeks each The fees for the four years respectively are \$500 each year The total registration for 1933 1934 was 294 graduates 70 The one hundred and tenth session begins Sept 19 1934 and ends June 1 1935 The Dean is Earl B McKinley M D

HOWARD UNIVERSITY COLLEGE OF MEDICINE Fifth and W streets NW—Chartered in 1867 Organized in 1869 The first class graduated in 1871 Coeducational since organization Negro students compose a majority of those in attendance The faculty comprises 30 professors and 63 lecturers and assistants 93 in all The admission requirements are at least two years of collegiate work including physics chemistry, botany and zoology English and French or German The course covers four years of thirty three weeks each The fees for each of the four sessions respectively are \$269 \$269 \$259 and \$266 Registration for 1933 1934 was 205 graduates 47 The sixty seventh session begins Sept 24, 1934, and ends June 7, 1935 The Dean is Numa P G Adams M D

## GEORGIA

### Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE 50 Armstrong Street and Druid Hills—Organized in 1854 as the Atlanta School of Medicine Classes graduated 1855 to 1861 when it suspended Reorganized in 1865 A class graduated in 1865 and each subsequent year except 1874 In 1898 it merged with the Southern Medical College (organized in 1878) taking the name of Atlanta College of Physicians and Surgeons In 1913 it merged with the Atlanta School of Medicine (organized in 1905) reassuming the name of Atlanta Medical College Became the

Medical Department of Emory University in 1915 assumed present title in 1917 Two years of collegiate work is required for admission The faculty consists of 19 professors and 168 associates and assistants a total of 187 The course of study is four years of thirty two weeks each The fees for each of the four years are \$300 Total registration for 1933 1934 was 225, graduates, 60 The next session begins Oct 1, 1934 and ends June 10 1935 The Dean is Russell H Oppenheimer, M D

## Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE University Place—Organized in 1828 as the Medical Academy of Georgia the name being changed to the Medical College of Georgia in 1829 Since 1873 it has been known as the Medical Department of the University of Georgia the name being changed July 1, 1933, to University of Georgia School of Medicine Property transferred to university in 1911 Classes were graduated in 1833 and all subsequent years except 1862 and 1863 Coeducation was begun in 1920 The faculty includes 41 professors and 26 assistants 67 in all Two years of collegiate work is required for admission The course is four years of thirty four weeks each The fees for each of the four years are \$185 for residents of Georgia and \$365 each year for nonresidents The total registration for 1933 1934 was 153 graduates 39 The one hundred and sixth session begins Sept 24, 1934 and ends June 10 1935 The Vice Dean is G Lombard Kelly M D

NOTE—Action of the Council on Medical Education and Hospitals Feb 11 1934 Resolved That approval of the University of Georgia School of Medicine be withdrawn at this time with the provision that this decision will not prejudice the transfer of the students now enrolled to class A medical schools at the end of the college session

Action of the Council June 10 1934 Resolved That in the resolution adopted in February 1934 the provision regarding transfer of students be amended so as to include those enrolled for the session of 1934 1935

## ILLINOIS

### Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Lincoln Street—Incorporated in 1915 as the Bennett Medical College and operated as an organic part of Loyola University by virtue of an agreement entered into with the trustees of Bennett Medical College Present title assumed in 1917 The Chicago College of Medicine and Surgery was purchased in 1917 The first class graduated in 1916 Coeducational Two years of collegiate work is required for admission The course of study is five years including an internship in a hospital The faculty is composed of 55 professors and 235 assistants lecturers instructors and others a total of 290 The fees for each year are \$371, \$407 \$334 and \$298 respectively The total enrollment for 1933 1934 was 460 graduates 89 The next session begins Sept 24 1934, and ends June 15, 1935 The Dean is Louis D Moorhead M D

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue—Organized in 1859 as the Medical Department of Lind University First class graduated in 1860 In 1864 it became independent as the Chicago Medical College It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891 when the present title was taken Became an integral part of Northwestern University in 1905 Coeducational since 1926 The faculty comprises 127 professors and 283 lecturers and assistants a total of 410 The requirements for admission are such as will admit to the College of Liberal Arts of Northwestern University plus three years of collegiate work, including courses in physics chemistry biology and a foreign language The course covers four years of eight months each and a fifth year spent in an approved hospital as an intern or in other practical work The total fees are \$365 each year The total registration for 1933 1934 was 548 graduates, 166 The seventy sixth session begins Oct 2 1934 and ends June 17 1935 The Dean is Irving S Cutter M D

UNIVERSITY OF CHICAGO RUSH MEDICAL COLLEGE 1758 West Harrison Street—Chartered in 1837 held first class in 1843 First class graduated in 1844 In 1887 the college became the medical department of Lake Forest University retaining however its self government This relation was dissolved in April 1898 and in the same month affiliation with the University of Chicago was established Coeducational since 1898 Since that time the work of the first two years has been given on the University Quadrangles In May, 1924, by a new contract the University of Chicago took over the work of Rush Medical College as a department of the university Thereafter only clinical work has been offered by Rush Medical College Since 1914 the course has included a fifth year consisting of a hospital internship or of a fellowship in one of the departments Three years of collegiate work is required for admission The year is divided into four quarters of twelve weeks each the completion of the work of three of these quarters gives credit for a college year The faculty is composed of 130 professors 148 associates instructors and others a total of 278 The fee for the third year is \$391 and for the fourth \$411 Total registration for 1933 1934 was 328 graduates 148 The nineteenth session begins Oct 1 1934, and ends June 11 1935 The school is in session all year except the month of September The Dean is Ernest C Irons, M D

UNIVERSITY OF CHICAGO THE SCHOOL OF MEDICINE OF THE DIVISION OF THE BIOLOGICAL SCIENCES Fifty Eighth Street and Ellis Avenue—Organized in 1924 The work of the first two years of the medical course has been given on the Quadrangles since 1899 in cooperation with Rush Medical College and that of the third and fourth clinical years was added in 1924 with the organization of this medical school and the construction on the Quadrangles of the university hospitals and clinics Coeducational A fifth year spent in successful internship in an approved hospital or in advanced work in some branch of medical science is required for the degree of M D The faculty is composed of 98 professors 132 associates, instructors and others a total of 230 The requirements for admission are three years of collegiate work The year is divided into four quar

## LOUISIANA New Orleans

**LOUISIANA STATE UNIVERSITY MEDICAL CENTER** 1532 Tulane Avenue—Organized January 1931 Coeducational First session October 1931 with students of first and third years Faculty comprises 32 professors and 117 assistant professors instructors and assistants a total of 149 Course covers four years of no less than 32 weeks each and one year of general rotation or laboratory internship in approved hospital A minimum of two years collegiate work is required for admission Begin work with the session 1935 1936 a minimum of three years collegiate Total fees \$92 each year for residents of Louisiana additional tuition of \$300 each year for nonresidents Total registration for 1933 1934 was 210 The fourth session begins Sept 19 1934 and ends June 1 1935 The Dean is Arthur Vidrine M D

**TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE** 1430 Tulane Avenue—Organized in 1834 as the Medical College of Louisiana Classes were graduated in 1835 and in all subsequent years except 1863 1865 inclusive It was transferred to the Medical Department of the University of Louisiana in 1847 and became the Medical Department of the Tulane University of Louisiana in 1884 Present title is 1913 Coeducational since 1915 The faculty comprises 35 professors and 125 associate and assistant professors instructors and assistants a total of 160 The course covers four years of thirty-two weeks each Two years of collegiate work is required for admission Total fees for each of the four years respectively are \$350 \$340 \$325 and \$355 The total registration for 1933 1934 was 496 graduates 123 The one hundred and one session begins Sept 28 1934 and ends June 12 1935 The Dean is Charles Cassidy Bass M D

## MARYLAND Baltimore

**JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE** Washington and Monument streets—Organized in 1887 Offered preliminary course only until 1893 The first class graduated in 1897 Coeducational since organization The faculty consists of 70 professors and 304 instructors assistants and others a total of 374 The requirements for admission demand that the applicant possess a collegiate degree and have a knowledge of French and German (two years each of college instruction) of physics and biology such as may be obtained from a year's course and a two years course in chemistry The course extends over four years and eight and one-half months each The total fees for each year are respectively \$611 \$610 \$610 and \$610 Total registration for 1933 1934 was 284 graduates 73 The forty second session begins Oct 2 1934 and ends June 11 1935 The Dean is Alan M Chesney M D

**UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS** Lombard and Greene streets—Organized in 1807 as the College of Medicine of Maryland The first class graduated in 1810 In 1812 it became the University of Maryland School of Medicine Baltimore Medical College was merged into it in 1913 In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed Coeducational since 1918 The faculty consists of 101 professors and 150 instructors and assistants a total of 251 Two years of collegiate work is required for admission The course covers four years of eight months each The fees for the four years respectively are \$410 \$400 \$400 and \$415 for residents of the state for nonresidents the fees are \$175 additional each year Total registration for 1933 1934 was 444 graduates 103 The one hundred and twenty seventh session begins Sept 21 1934 and ends June 1 1935 The Dean is J M H Rowland M D

## MASSACHUSETTS Boston

**BOSTON UNIVERSITY SCHOOL OF MEDICINE** 80 East Concord Street—Organized in 1873 as a homeopathic institution In 1874 the New England Female Medical College founded in 1848 was merged into it The first class was graduated in 1874 Became nonsectarian in 1911 Coeducational since organization Three years of collegiate work is required for admission The faculty includes 22 professors 153 associate and others a total of 175 The course covers four years Total fees for each of the four years respectively are \$426 \$421 \$421 and \$406 Total registration for 1933 1934 was 246 graduates 53 The sixty second session begins Sept 20 1934 and ends June 10 1935 The Dean is Alexander S Begg M D

**HARVARD UNIVERSITY MEDICAL SCHOOL** 25 Shattuck Street—Organized in 1782 The first class graduated in 1788 It has a faculty of 136 professors and 359 other instructors and assistants a total of 495 Candidates for admission must present a college degree The college work must include a year of physics biology general chemistry organic chemistry and a reading knowledge of French or German The college work for each of the four years is \$400 plus \$5 the first year for matriculation The total registration for 1933 1934 was 516 graduates 132 The one hundred and fifty second session begins Sept 24 1934 and ends June 20 1935 The Dean is David L Edsall M D

**TUFTS COLLEGE MEDICAL SCHOOL** 416 Huntington Avenue—Organized in 1893 as the Medical Department of Tufts College The first class graduated in 1894 Coeducational since 1894 It has a faculty of 65 professors and 240 assistants lecturers and others a total of 305 A bachelor's degree is required for admission The course covers four years of eight months each The total fees for each of the four years are \$412 \$407 \$407 and \$417 Total registration for 1933 1934 was 468 graduates 101 The thirty ninth session begins Sept 26 1934 and ends June 17 1935 The Dean is A. Warren Stearns M D

ters of twelve weeks each the completion of the work of three of these quarters gives credit for a college year Students are admitted at the beginning of the autumn quarter The tuition fees for each of the four years are \$375 Total registration for 1933 1934 was 325 graduates 19 The next session begins Oct 1 1934 and ends June 12 1935 The Dean of Medical Students is B C H Harvey M D

**UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE** 1853 West Polk Street—Organized in 1882 as the College of Physicians and Surgeons The first class graduated in 1883 It became the Medical Department of the University of Illinois by affiliation in 1897 Relationship with the university was canceled in June 1912 and was restored in March 1913 when the present title was assumed Coeducational since 1898 Two years of collegiate work is required for admission The curriculum covers four years of thirty-two weeks each and a year of internship in an approved hospital The faculty is composed of 112 of professional rank and 250 assistants and instructors a total of 362 The tuition is \$200 a year for students who are residents of Illinois \$300 a year for nonresident students The total registration for 1933 1934 was 640 graduates 115 The fifty third session begins Oct 1 1934 and ends June 7 1935 The Dean is David John Davis M D

## INDIANA

### Bloomington-Indianapolis

**INDIANA UNIVERSITY SCHOOL OF MEDICINE**—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905 In 1907 by union with the State College of Physicians and Surgeons the complete course in medicine was offered In 1908 the Indiana Medical College which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878) the Central College of Physicians and Surgeons (organized in 1879) and the Fort Wayne College of Medicine (organized in 1879) merged into it The first class was graduated in 1908 Coeducational since organization The faculty consists of 270 professors lecturers associates and assistants Two years of collegiate work is required for admission The work of the first year is given at Bloomington and the work of the next three years at Indianapolis The regular fee for the medical course at Bloomington is \$205 a year for residents of Indiana \$410 for nonresidents The regular fee for the medical course at Indianapolis for students now enrolled and in residence is \$175 a year for residents of Indiana and \$350 for nonresidents The total registration for 1933 1934 was 465 graduates 116 The next session begins Sept 18 1934 and ends June 17 1935 The Dean at Bloomington is Burton D Myers M D and the Dean at Indianapolis is Willis Dew Gatch M D

## IOWA

Revised to Aug 2, 1934

The following general hospitals containing 211 705 beds are considered in position to furnish acceptable internships for medical graduates

## HOSPITALS, 676 INTERNSHIPS, 6,204

The terms used in the column Type of Internship are defined as  
 1 Rotating internships include services in medicine surgery pediatrics obstetrics and in the clinical and x-ray laboratories  
 2 Straight internships are limited to a single field  
 3 Mixed internships are those comprising more than one service but which do not include all of the six branches which constitute a rotating internship

# HOSPITALS APPROVED FOR RESIDENCIES IN SPECIALTIES

By the Council on Medical Education and Hospitals of the American Medical Association

Revised to Aug 20, 1934

**NOTE**—The following hospitals are considered in position to furnish acceptable residencies in the several specialties designated, for graduates who have already had a general internship or its equivalent in practice. A list of hospitals approved for internships will be found on page 588. Statistical material is based on reports received for the calendar year 1933. Reported salaries should be verified through correspondence with individual hospitals.

The abbreviations under the column headed "Control" are as follows:

Chrch Co	Church City and county County	Fed Frat Indep	Federal Fraternal Independent hospital association	Indlv Indus USPH	Individual Industrial United States Public Health Service

SATURDAY, AUGUST 25, 1934

## THE ADMINISTRATION STUDIES SOCIAL INSURANCE

In the message that he gave to the American people just before leaving for Hawaii, President Franklin D. Roosevelt indicated his interest in social insurance, including all means of securing the worker against every type of misfortune or natural disability that might occur to him. Unemployment, sickness, old age and death are obviously the major difficulties that might occur to almost every man. Perhaps a more complete interpretation of the President's point of view was offered by Secretary of Labor Frances Perkins in a radio address, August 13. She indicated that the major objective of the national administration has been economic recovery and that this will continue to be the principal objective until recovery is complete. Before departing on his vacation, however, the President created a committee of cabinet and other officials on economic security. Of this committee Miss Perkins is chairman, the remaining members including the Secretary of the Treasury, the Secretary of Agriculture, the Attorney General and the Federal Emergency Relief Administrator. This committee has now appointed a technical board to study the questions and to advise it in formulating legislation for presentation to the next Congress. Of this board the executive director is Edwin E. Witte, labor economist long connected with the industrial commission and the legislative reference service of the state of Wisconsin. The staff already includes Mrs. Barbara Nachtrieb Armstrong of the University of California, author of "Insuring the Essentials," Edgar Sydenstricker and Dr. Bryce Stewart of New York. Miss Perkins states that the President is expected in the near future to name an advisory commission composed of representative citizens from all parts of the country to aid still further the development of the program for economic security.

After discussing the importance of protection of the worker, Miss Perkins pointed out that "our best hope for protecting the worker against the hazards and vicissitudes of life lies in the application of the principles of insurance." She pointed out that forty-four states

now have workmen's compensation laws, forty-six states have mothers' pension laws, and twenty-eight states have old age pension laws. She emphasized the fact that some provisions are now being made for medical and hospital care to indigents through relief and other agencies. She said, however, that when all of our methods for providing economic security are brought together, they do not begin to meet the needs of the situation. The Committee on Economic Security was therefore developed to work out some plan for solving the difficulties.

Miss Perkins indicated that it is not possible to present a comprehensive program of social insurance to cover farmers and self-employed people as well as wage earners for the next Congress, although she recognized great advantages in a unified system of social insurance presented in one complete whole. She pointed out that she had suggested a program for social action in New York twenty years ago and that all but one of the items then suggested were now in operation in that state. The appointment by the President of the Committee on Economic Security is assurance that the President intends to go ahead with his program, and the committee interprets the executive order that created it as a mandate to survey the entire field and outline a complete program for economic security.

Thus the point of view of the administration is clearly set forth and it remains for the medical profession to make certain that its point of view in relationship to medical practice is fully understood by the committee. At the annual session of the American Medical Association in Cleveland, ten principles for the guidance of the medical profession in setting up any plan were unanimously adopted. The medical profession, in setting forth these principles, aims to protect the quality of medical service rendered to the people and to safeguard the relationship between patient and physician which is fundamental to the best type of medical practice. The staff of the technical board developed by the Committee on Economic Security thus far named is not such as to warrant any expectation of recognition of the medical point of view by the committee. Indeed, the views of Sydenstricker, a member of the staff of the Milbank Foundation, are so completely antagonistic to the medical point of view that one wonders why he should have been among the first to be selected by the committee in developing its work. In the address that he made before the American Academy of Political and Social Science in Philadelphia, February 7, Sydenstricker indicated his opposition to our entire economic system. Thus he said "Any program of action to be given serious consideration at present must assume the continuance of the economic system under which we now live—a system that is characterized by a grossly unequal distribution of wealth and an inability to pay for the essentials or luxuries of life." Mr. Sydenstricker's answer to the problem of medical care is an insurance system that will go

beyond the systems already established abroad and provide every type of medical service to every member of the family of people having incomes below the amount that is sufficient to purchase medical service in any contingency

In a more recent statement, in the *Literary Digest* for July 7, Mr Sydenstricker begins to modify his views or perhaps to change them because of the nature of his new audience. He urges, now, a very gradual development of new methods without disturbing too much our present system of practice. Notwithstanding this softening of the proposals emanating from the Milbank Foundation, the medical profession will not consider itself adequately represented in the development of any plan for sickness insurance by the group involved if Mr Sydenstricker is the only authority on what constitutes proper arrangements for medical care.

In the discussions of this topic that have been carried on during the last ten years, a rather definite alignment of students of the subject has taken place according to their points of view. THE JOURNAL has repeatedly listed those who may be considered as definitely opposed to the policies of the organized medical profession, which embraces almost every competent physician in the United States. The medical profession will probably find it difficult to lend its approval to any plan or system developed by any committee or group that not only fails to include representatives of the medical profession but thus far has failed even to give adequate opportunity to the medical profession to present its point of view officially in these matters. It is to be hoped that the American medical profession merits enough recognition from our government to cause that government to seek its advice and its assistance in the development of these plans from the very first step in the consideration

### AORTIC STENOSIS

The opening from the left ventricle into the aorta is closed during diastole by the aortic semilunar valves. Whenever these three valves become stiffened or fused by disease, the opening into the aorta is narrowed and the free flow of blood from the ventricle is obstructed. True aortic stenosis has been considered rare. Heart disease has, however, become the leading cause of death, and it may be that aortic stenosis occurs more frequently than has been supposed. In reviewing 6,800 necropsy reports of all types of disease at the Massachusetts General Hospital, McGinn and White<sup>1</sup> found 123 cases of aortic stenosis. In a clinical group of 4,800 cardiovascular cases they found 113 cases of aortic stenosis. The incidence in the two groups was therefore 1.8 and 2.3 per cent, respectively, which was higher than had been anticipated.

Since the basal cardiac area has been called the field of romance in diagnosis, it is not strange that the

criteria for a diagnosis of aortic stenosis have changed in the last generation. When a basal systolic murmur alone permitted a diagnosis of aortic stenosis, the lesion was diagnosed too frequently. Then followed an over-cautious period when the criteria required were a loud aortic systolic murmur, an aortic systolic thrill, absence of the second aortic sound, a plateau or anacrotic pulse, and perhaps an aortic diastolic murmur. The preferable diagnostic position, McGinn and White have found, lies between these extremes. The diagnosis may be justified when there is a harsh and loud aortic systolic murmur transmitted to the neck, whether or not it is accompanied by the foregoing confirmatory signs. A loud systolic murmur in the second right interspace should suggest aortic stenosis when there is evidence of other valvular defects or a history of rheumatic infection and when evidence of syphilitic aortitis or of marked hypertension is absent. It is interesting that a clinical diagnosis had been made in only one third of the 123 cases of aortic stenosis found among the 6,800 necropsies. Aortic stenosis is missed much more often when it is present, the Boston investigators believe, than it is diagnosed when it is absent. A clinical diagnosis of aortic insufficiency was frequently made in this series of cases, in fact, that lesion also was present in fifty-two of the aortic stenosis cases that came to necropsy. About every third case of mitral stenosis in the necropsy group also presented aortic stenosis. In the clinical group the ratio was much lower, but in the second half of this group, when perhaps the investigators were more zealous, twice as many cases of aortic stenosis were discovered as in the first half of the series.

There was a history of an important infection in one third of the necropsy cases of aortic stenosis and in one half of the clinical cases. The infections most frequently recorded were tonsillitis, pneumonia, influenza, typhoid and gonorrhea. Syphilis was not diagnosed in any case in the clinical series and in only four cases in the necropsy series.

The patients complained commonly of dyspnea, orthopnea and edema, and of faintness or dizziness or actual syncope. About 19 per cent of the patients had angina pectoris and 15 per cent cardiac asthma. The pulse was described as normal in the majority of these cases. A Corrigan pulse was noted in only twelve cases in the entire series, and a plateau pulse was noted in only nine cases. The diastolic blood pressure varied between 80 and 110 mm of mercury. The average pulse pressure was unexpectedly high, 60 mm of mercury. There was cardiac enlargement to the left, found in all but ten of the total number of cases. Sometimes the fluoroscope would reveal the calcified aortic valves. The most common observation in the electrocardiogram was left axis deviation, although in some cases it was not present. Abnormal T waves exclusive of the bundle branch block cases were present in sixty-six of the 110 electrocardiograms.

<sup>1</sup> McGinn, Sylvester and White, P. D. Clinical Observations on Aortic Stenosis. *Am. J. M. Sc.* 188:1 (July) 1934.

Of the 236 patients with aortic stenosis, 172 were known to be dead, twelve died following operations and nine others died suddenly. The majority died of congestive heart failure. The average number of attacks of congestive failure was two.

From this study it is evident that all grades of aortic stenosis exist. The lesion is not uncommon, especially in males. While it is less serious than aortic regurgitation, aortic stenosis is important even if mild, because of the progressive nature of the lesion and because of its association with congestive heart failure. The detection of such cases is clearly dependent on the fine application of the physical diagnostic art. The making of a correct diagnosis in only one third of the instances established post mortem is an indication of the necessity for more attention to this phase of medical practice.

#### THE NEW AMERICAN MEDICAL DIRECTORY

After fourteen months the work of compiling and printing the Thirteenth Edition of the American Medical Directory has been completed and copies are now available for general distribution. The importance of this volume as a source of authoritative data of the medical profession and its allied interests is widely recognized.

The 1934 directory contains 2,451 pages and lists 178,516 physicians in the United States, its dependencies, Canada and Newfoundland, and American graduates and licensees temporarily practicing in foreign countries. It supplies also information regarding the medical practice acts of various states, the Constitution, By-Laws and Principles of Medical Ethics of the American Medical Association, the membership of special organizations of physicians, and the names and locations of medical schools, medical journals, medical libraries, state institutions, hospitals, sanatoriums and charitable institutions. All the information is verified and in form for convenient reference.

Three years has passed since the Twelfth Edition appeared. More than 92,541 changes of address have been made, 18,727 names of new physicians added and 11,473 dropped from the book on account of death. These figures, however, do not include the thousands of changes in society affiliations, teaching positions in medical schools, and specialties.

The Atlantic and Pacific states show the largest increase in the number of physicians. The Central and Southern states, with the exception of Wisconsin and Texas, are practically unchanged or show losses. This is probably accounted for by the continuation of physicians to locate in larger cities and the migration of physicians from rural districts to more thickly populated centers. Good roads have made it possible for physicians to widen their areas of practice. In the states showing increases, New York leads the list with

a gain of 1,804, the 1931 edition contained 21,008 physicians, while the 1934 edition has 22,812. Other states with noticeable gains are New Jersey, Pennsylvania, Maryland, California, Texas, Wisconsin and Connecticut. The seventeen states that show losses are Arkansas, Alabama, Kentucky, Indiana, Kansas, Maine, Missouri, Montana, South Dakota, Arizona, Colorado, Georgia, Mississippi, Nebraska, North Dakota, Oklahoma and West Virginia. The first nine of these are farm states or have a large rural population. Arkansas in 1914 had 2,652 physicians, today it has only 1,890. Among the twenty-six largest cities in the United States, New York is in first place with a gain of 596 physicians and Kansas City, Mo., is in twenty-sixth place with a loss of 65.

In 1914 the total number of physicians listed in the Directory was 153,496, in 1925, 161,358, in the new 1934 edition the number is 178,516. The average yearly gain for the first eleven years was 714, for the last nine years it was 1,906. This increase is due to the larger number of graduates from American medical schools.

The Directory, or Biographical Department, as it is often referred to, was established in 1905. At that time the only national directories in existence were those published as private enterprises and for profit. Usually the only data given were the name, address and medical school, but any physician could, by payment of a fee or even by merely subscribing to the book, have several inches of flattering, and oftentimes untruthful, information printed about himself. A goodly portion of this display advertising was paid for by physicians of questionable character. Space in the American Medical Directory cannot be bought. All the basic information is checked and verified from official sources. Not only the name, address and medical school of the physician are given but also his year of birth, year of licensure in the state in which he is located or practicing, specialty, society affiliations and teaching positions. To save space, much of the information is expressed in keys and symbols. A general knowledge of the exact meanings of these abbreviations can easily be gained by referring to the front inside cover and pages 6 and 7 of the Directory. However, to get the best service the introductory contents and the various indexes should also be carefully consulted.

The Directory continues the policy in this issue of publishing in connection with each state and the provinces of Canada a list of those hospitals ethically operated in accordance with the "Essentials of a Registered Hospital." Altogether the principal facts concerning 6,612 hospitals in the United States and 754 in Canada and Newfoundland are presented. Separate lists of hospitals approved for internships and for residencies in specialties are to be found on pages 95 to 114, and indicated by proper symbols in the lists of hospitals in connection with the various states. All

these institutions have been carefully investigated and have been found to present suitable programs for advanced training during the internship and subsequent years of medical education

Other useful information given, relating to the medical profession, are lists of medical officers in the government service, licensing boards, state boards of health, county and district health officers, officers of constituent state medical associations and component county and district medical societies

Careful attention has been given to the typography of the book to keep it condensed and yet easy to read. For example, the surnames appear in the index in boldface type, which expedites locating the physicians. While the book is only forty-five pages larger than the previous edition, it includes 6,167 more names than the last directory

To the secretaries of the various medical licensing boards of the United States and Canada, to the deans of medical schools, to the officers of component county societies and constituent state associations, to the thousands of physicians and correspondents who have so cordially assisted in making possible this edition, the Biographical Department extends thanks and appreciation

## Current Comment

### RECENT ACTIVITIES OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The first classification of medical schools by the Council on Medical Education and the Carnegie Foundation's report on medical teaching were published a quarter of a century ago. The resulting improvement in the standards of medical education in the United States is without a parallel in history. This transformation should not blind one to the fact that much remains to be done to keep the training of physicians fully abreast of the medical and scientific knowledge of the times. In order to ascertain what is the current practice of the medical schools of the United States and Canada, the Council is undertaking a comprehensive and intensive resurvey of the institutions engaged in medical teaching. By correspondence and by personal visits an effort will be made to get a trustworthy record of the work of each school. Special attention will be paid to the qualifications of the faculty and the effectiveness of clinical teaching. Inspections will begin as soon as schools open in the fall. Supplementing this objective study, the Council is also planning a reappraisal of the aims and methods of medical teaching. To aid in the formulation of standards and policies, an advisory committee has been created, which includes in its membership representative leaders in the field of medical education. Cooperation of the Association of American Medical Colleges and the Federation of State Medical Boards has also been secured. These

activities of the Council give definite promise of bettering the standards of medical practice. The need for this new work is a reply to those who have urged that the Council on Medical Education had completed the task for which it was founded. The necessity for constant vigilance demands the maintenance of this body as a protection to both the public and the medical profession

### MISREPRESENTATION

Just as long as the antivivisectionists permit their activities to be motivated emotionally rather than rationally, they continue to expose the extreme weakness of their arguments. A particularly flagrant example of distortion of fact has come to light in connection with an editorial in a recent issue of *THE JOURNAL*.<sup>1</sup> A liberal excerpt of the original statement follows

To many it may seem strange that in this day "laboratory medicine" needs any apologies or defense. Yet not long ago Mendel<sup>2</sup> of Yale University said that there are today not a few physicians as well as other friends of medicine who, although admitting the noteworthy contributions of animal experimentation, nevertheless urge that its dominant importance is passing. Though the pendulum of enthusiasm for a laboratory innovation may at times swing too far, it soon reaches a stable level. In his defense of scientific experimentation in medicine, Mendel made a vigorous plea that devotees of practical medicine and surgery refrain from unwarranted derogatory attacks on one of the best helps of their profession in the past. It is difficult enough, he added, to fight suffering, disease and death without being obliged to fight the ignorance and prejudices of those who would tie the arms of the laboratory worker

To a mature individual with ordinary education and the ability to understand clear English, the meaning conveyed by the foregoing quotation is inescapable. Yet in the July 1934 issue of the *Starry Cross*, the official organ of the American Antivivisection Society, there appears in the column entitled *Heard and Read* the following comment

A surprising editorial in the *Journal of the American Medical Association* (May 26, 1934) quotes L. B. Mendel of Yale University to the effect that "There are today not a few physicians as well as other friends of medicine who, although admitting the noteworthy contributions of animal experimentation, nevertheless urge that its dominant importance is passing." This is a great deal for a pro-vivisectionist to admit publicly, and is a welcome indication that the vivisectioning profession is being forced to admit, however slowly, that its boosting of vivisection is bringing it into wider and wider disrepute with a consequent disastrous effect upon medical pocketbooks and reputations. It is safe to say that when the profession at large does awake from its self-induced delusions regarding the cruel and disgraceful practice of vivisection it will turn its back upon the once-vaunted "scientific research" as completely and with the same scorn as that accorded its other fads of yesterday

A comparison of the two quotations is sufficient comment on the methods of misrepresentation employed by the antivivisectionist. It provides another example of the tendency of the "will to believe" to becloud intellectual integrity

<sup>1</sup> Hyperparathyroidism. A Chapter in Successful Laboratory Research editorial J A M A 102:1764 (May 26) 1934

## Association News

### MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central daylight saving time. The next three broadcasts will be as follows:

August 30 Your Child Enters School Morris Fishbein, M D  
September 6 Football Hazards Morris Fishbein M D  
September 13 Common Eye Troubles, William C Benedict M D  
representing the meeting of the American Academy of Ophthalmology and Otolaryngology, in Chicago

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION, PUBLIC HEALTH ETC.)

### ALABAMA

Personal—Dr Coleman D McLeod, Fairfield, has been appointed health officer of Covington County, with headquarters at Andalusia.—Dr Ernest G Moore, Whitley, has been made health officer of Bullock County, succeeding Dr William A Stanley, who has gone to Coffee County in the same capacity.

### CONNECTICUT

Resolution Urges Prohibition of Fireworks—The sale and use of fireworks in New Haven are disapproved in a resolution unanimously adopted by representatives of civic organizations and the board of health, July 18. The resolution requests the board of aldermen of the city to enact a suitable ordinance prohibiting the sale and use of fireworks.

Clinical Congress of State Society—The Connecticut State Medical Society will conduct its tenth clinical congress in New Haven September 18-20. On the program will be the following physicians:

George E Bennett Baltimore Symptomatology Diagnosis and Treatment of Lumbosacral and Sacro Iliac Strain  
Russell L Cecil New York Treatment of Arthritis from the Clinical Standpoint  
Robert B Osgood Boston Etiologic Theories and Therapeutic Trends in Chronic Arthritis  
Frank R Ober Boston Diagnosis and Treatment of Common Disabilities Causing Pain in the Upper Extremity  
Howard Fox New York Diagnosis and Treatment of Common Skin Diseases  
Francis G Blake New Haven, Treatment of Pneumococcal Lobar Pneumonia with Special Consideration of the Use of Antipneumococcus Serum and Artificial Pneumothorax  
Percy S Pelouze Philadelphia Gonorrhea in the Male and Its Treatment  
Oscar M Schloss New York Pathogenesis of Pyuria in Early Life  
Alfred Stengel Philadelphia, Psychoses Complicating Other Diseases  
Stanhope Bayne Jones New Haven Prophylactic Vaccination  
Max A Goldzieher New York Diagnosis of the Ordinary Endocrine Disorders  
Alexander B Gutman New York Therapeutic Uses of Parathormone  
Carl H Greene New York Therapeutic Use of the Cortical Hormone of the Suprarenal Gland  
John Rock Boston Useful Endocrine Preparations in Gynecology  
C Macfie Campbell Boston Importance of the Consideration of the Personality in General Practice

Afternoon sessions each day will be devoted to demonstrations and round table discussions on subjects presented at morning sessions. Dinner meetings have been omitted this year and the scientific program will be continued into the evenings of the first two days of the congress. The registration fee has been reduced to \$2. Dr Creighton Barker, 129 Whitney Avenue New Haven, is chairman of the committee on publicity and registration.

### DISTRICT OF COLUMBIA

Personal—Dr Ralph L Lawrence has been promoted and commissioned as a surgeon in the regular corps of the U S Public Health Service, to rank as such from June 30.

Health Council Established—The District of Columbia Health and Hospital Council, composed of representatives of medical, dental and civic societies, was recently formed under the sponsorship of the Council of Social Agencies. The council

will be available to all government authority as a medium of ascertaining opinion and reaction of the majority in professional, administrative and lay organizations representing the citizens in the district, according to a statement issued by Ross Garrett, health secretary of the Council of Social Agencies. Physicians who have volunteered to serve on the new health council include Drs Adolphus B Bennett, Prentiss Willson, William H Hough, Charles R L Halley, William Charles White, Loren B T Johnson, Arthur C Christie, J Russell Verbyck Jr, Thomas A Groover, Henry C Macatee, William J Thompkins and Paul B Cornely. C Willard Camaler, DDS, G Albert Smith, DDS, and Webb W Wyman, DDS, are dentists named on the committee.

### IDAHO

State Medical Meeting at Lewiston—The annual session of the Idaho State Medical Association will be held in Lewiston, September 7-8. Speakers will be:

Dr Verne C Hunt Los Angeles Operability of Carcinoma of the Stomach Surgical Procedure Involving the Common Duct in Biliary Tract Disease  
Dr William D Stroud Philadelphia Coronary Disease Digitalis in Treatment of Cardiovascular Disease from the Standpoint of the General Practitioner  
Dr Thomas F Mullen San Francisco Plastic Reconstruction of the Esophagus  
Dr Henry Odland Seattle Wash Problems in the Treatment of Eczema  
Dr Montague S Woolf San Francisco A Critique of the Operations in Vogue for Cancer of the Rectum  
Dr Hale A Haven Seattle Differential Diagnosis of Spinal Cord Tumors  
Dr Joseph A Pettit Portland Ore  
Dr Eugene L Spohn Coeur d Alene Care of County Indigent  
Dr Duncan Alexander Twin Falls

Dr Olin West, Chicago Secretary, American Medical Association will address a scientific session, September 7, and the annual banquet in the evening.

### ILLINOIS

Health at Peoria—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended August 11, indicate that the highest rate (188) appears for Peoria and the rate for the group of cities as a whole was 97. The death rate for Peoria for the corresponding week of 1933 was 124 and for the group of cities, 92. The annual rate for the eighty-six cities for the thirty-two weeks of 1934 was 118, as against a rate of 112 for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

### Chicago

Health Lectures at A Century of Progress—The following lectures will be delivered by members of the Chicago Medical Society during the week beginning August 27, as a part of the regular series sponsored each week at A Century of Progress by the society:

August 27 Melvin R Guttman Hoarseness A Warning Sign of Cancer  
August 28 (Not announced)  
August 29 Cleveland J White The Ringworm Situation  
August 30 Joseph E Schaefer Infections of the Mouth  
August 31 Frederick C Test Feet and Posture  
September 1 Charles Drucek Poisoning from the Bowels

### INDIANA

Society News—Dr John A Ritchey, Jonesboro, addressed the Grant County Medical Society in Marion, July 24, on allergy.—Dr Jean P Pratt, Detroit, will address the Tippecanoe County Medical Society, Lafayette, September 13, on "Endocrine Disturbances Peculiar to Women." A clinic on endocrine disturbances will be held at St Elizabeth's Hospital in the afternoon.—The Hamilton County Medical Society at its monthly meeting, July 6, entertained, among others, members of the county council, county commissioners, trustees, two Noblesville ministers, trustees of the Hamilton County Hospital, Noblesville, and several of the laymen. A banquet was served at the hospital.

Free Arsphenamine for Indigents—A plan was recently adopted by the Indiana Division of Public Health whereby free neoarsphenamine and sulpharsphenamine are furnished to physicians for the treatment of indigent infectious syphilitic patients who may endanger other persons, the *Journal of the Indiana State Medical Association* reports. Under this plan, patients are to be treated until they are noninfectious and no longer a menace to public health. The division also intends to furnish serum to expectant mothers infected with syphilis.

during pregnancy. It was pointed out that in communities where public health clinics are available, or where clinics are being operated at the expense of the city or city and county, indigent patients are expected to report directly to the clinic for antisyphilitic treatments.

### KENTUCKY

**State Health Agency Reorganized**—Under a reorganization bill passed by the last legislature, the state board of health will henceforth be known as the State Department of Health of Kentucky and the state health officer becomes the state health commissioner. A board of health will elect the commissioner, who will serve as secretary of the board. Registrations in the professions allied with medicine will be conducted by the same boards as before, but these boards will be divisions of the department of health, as will the Crippled Children's Commission.

**Society News**—Dr Clifford N. Heisel, Covington, addressed the Grant County Medical Society, Williamstown, June 20, on "Diagnosis of Acute Mastoid Conditions."—Drs. Walter E. Vest and Robert J. Wilkinson, Huntington, W. Va., addressed the Lawrence County Medical Society, Louisa, recently, on abscess of the lung and cancer of the breast, respectively.—Dr. Noah H. Short, Norton, Va., read a paper on sinusitis at a recent meeting of the Letcher County Medical Society, Whitesburg.—Drs. Oscar O. Miller and George A. Hendon, Louisville, presented a course of lectures under the auspices of the Kentucky State Medical Association before the Henry County Medical Society at Eminence, August 16. Dr. Miller discussed various phases of tuberculosis, and Dr. Hendon, fracture of the hip, peptic ulcer, appendicitis and acute intestinal obstruction.—Physicians of northeastern Kentucky attended a meeting in Ashland August 1, sponsored by the Kentucky State Medical Association, at which uterine cancer was discussed by Drs. L. Wallace Frank, Charles D. Enfield and William C. Martin, Louisville.

### MAINE

**Rabies Among Foxes**—Ten foxes with evidence of rabies have been killed in an area of eight square miles in Franklin and Somerset counties, the *New York Times* reported August 4. Health and game authorities of the state ordered trappers and expert marksmen to shoot all foxes on sight. Several children and domestic animals had been bitten. All the foxes killed exhibited behavior typical of hydrophobia and in one case the presence of the disease was confirmed by laboratory examination.

### MASSACHUSETTS

**Personal**—Dr. George L. Stivers, for three years medical director of Belmont Hospital, Worcester, has been appointed medical director of the Fall River Hospital, Fall River.—Dr. Elmer W. Barron has been appointed physician in chief of the visiting and consulting staff of the Boston Floating Hospital.

### MICHIGAN

**Acting Secretary of State Society**—The Michigan State Medical Society announces that on and after September 1 Dr. Burton R. Corbus, Grand Rapids, will be acting secretary of the society. Dr. Frederick C. Warnshuis, Grand Rapids, after many years as secretary, has resigned to become secretary of the California Medical Association. After October 1 Dr. Warnshuis' address will be Room 2004, 450 Sutter Street, San Francisco.

**State Medical Meeting at Battle Creek**—The one hundred and fourteenth annual meeting of the Michigan State Medical Society will be held in Battle Creek, September 11-13. Dr. Walter L. Bierring, Des Moines, Iowa, President of the American Medical Association, will address the opening general meeting Wednesday morning, September 12. Guest speakers who will address the scientific sessions include:

- Dr. William A. Thomas, Chicago: Acute Hepatic Insufficiency with Special Reference to Liver Function Tests and Therapy.
- Dr. Joseph L. Baer, Chicago: Uterine Fibroids: Their Treatment and Some Correlated Factors.
- Dr. Elliott C. Cutler, Boston: Surgery in the Management of Heart Disease: Preoperative and Postoperative Treatment of the Toxic Thyroid Patient.
- Dr. Peter A. Bendixen, Davenport, Iowa: Fracture of the Lower Extremity.
- Dr. Loyal Davis, Chicago: Treatment of Cerebrospinal Injuries.
- Dr. Perrin Hamilton, Long Beach, California: Value of Prophylactic Methods in Prevention of Common Colds.
- Dr. Williams McKim Marriott, St. Louis: Conditions in Childhood Associated with Hypoglycemia.
- Dr. Marion B. Sulzberger, New York: Allergy in Dermatology.

All sessions will be held at the W. K. Kellogg Auditorium, and the Kellogg Hotel will be headquarters.

### MINNESOTA

**Dr. Parker Returns to Ireland**—Dr. Harry Lee Parker, associate professor of neurology, Mayo Foundation, University of Minnesota, Rochester, has resigned to return to Ireland as chief of staff of the Neurologic Institute of Southern Ireland and professor of neurology, Trinity College, University of Dublin. Dr. Parker is a graduate of the University of Dublin and has been associated with the Mayo Foundation since 1919.

**Masseur Prescribes a Diet**—The license of Leonard James Chmel to practice massage in Minnesota will not be renewed, in accordance with a decision of the state board of medical examiners, July 14. Early in January a complaint was made to the board about treatment administered by Mr. Chmel to a patient in Minneapolis who was afflicted with asthma. Testimony showed that the patient was kept on an orange juice and beef broth diet by Mr. Chmel for five weeks, at the end of which time a physician was called. In 1930 Chmel appeared before the board to show why his license should not be renewed, at that time he was using the titles of "doctor" and "naprapath."

### MONTANA

**State Medical Election**—Dr. Louis H. Flugman, Helena, was named president elect of the Medical Association of Montana at the recent annual meeting in Helena. Dr. Charles E. K. Vidal, Deer Lodge, became president, Dr. Ashley W. Morse, Butte, vice president, and Dr. Elmer G. Balsam, Billings, was reelected secretary. The next annual session will be held in Billings, July 10-11, 1935.

### NEBRASKA

**Study of Eskimo Children**—Dr. Victor E. LeVine, professor and head of the department of biological chemistry and nutrition and Charles W. Bauer, A.M., professor of chemistry, Creighton University, Omaha, are spending four months in Alaska in a study of Eskimo children. The investigators are making physical measurements and determining the nutritional status and basal metabolism of the children. Quantitative studies of the children's blood for inorganic constituents are being made and their susceptibility to tuberculosis, diphtheria and scarlet fever is being tested.

### NEW YORK

**Personal**—Dr. Thomas Parran, Jr., Albany, state health officer, received the honorary degree of doctor of laws at the hundredth anniversary of Syracuse University School of Medicine June 4.—Fred R. Griffith, Jr., Ph.D., professor of physiology at the University of Buffalo School of Medicine has been appointed head of the department to succeed Frank A. Hartman, Ph.D., who recently resigned to go to Ohio State University College of Medicine.

**Hospital Superintendent Appointed**—Drs. Noah Stanley, Lincoln, and Ralph Horton of the staff of the division of tuberculosis, state department of health, have been provisionally appointed superintendents of two of the new state tuberculosis hospitals now under construction. Dr. Lincoln will have charge of the Hermann M. Biggs Memorial Hospital at Ithaca, and Dr. Horton of the new hospital at Oneonta. Drs. Edmund H. Kerper, Loomis, and Aloysius D. Maby, Albany, have been provisionally appointed to succeed Drs. Lincoln and Horton in the state health department.

### New York City

**Changes at Rockefeller Institute**—Dr. Warfield T. Longcope, Baltimore, has been elected a member of the board of scientific directors of the Rockefeller Institute for Medical Research to succeed Dr. William H. Welch. Dr. Leslie T. Webster has been promoted to membership in the institute, Dr. Richard E. Shope to associate member, Dr. Francisco Duran-Reynals, Kenneth Goodner, Ph.D., and Geoffrey W. Rake, to associate, and Kenneth S. Chester, Ph.D., Erich Traub, M.D., and Philip R. White, Ph.D. to assistant. Max Bergmann, Ph.D. has been appointed associate member. The following new assistants have also been appointed:

- |                           |                        |
|---------------------------|------------------------|
| Donald C. Boughton, Ph.D. | Jack Compton, Ph.D.    |
| Dr. James R. Dawson, Jr.  | Dr. Lee E. Farr        |
| Dr. Delavan V. Holman     | Dr. John G. Kidd       |
| Dr. Colin M. MacLeod      | Dr. Thomas F. M. Scott |
| Mr. William F. Ross       | Dr. Joseph E. Smadel   |
| Carl V. Smythe, Ph.D.     |                        |

The following were appointed fellows:

- |                        |                            |
|------------------------|----------------------------|
| Bacon F. Chow, Ph.D.   | Joseph F. Fruton, Ph.D.    |
| George I. Lavin, Ph.D. | Dr. Charles V. Seaton, Jr. |
| William Trager, Ph.D.  |                            |

## NORTH CAROLINA

**Changes in Health Department Staff**—Dr Joseph C. Know, assistant epidemiologist of the state board of health, Raleigh, has been appointed epidemiologist, succeeding Dr Daniel F. Milam, who has been transferred to Panama by the International Health Board of the Rockefeller Foundation. He was assigned as consulting epidemiologist to North Carolina two years ago. Dr Robert E. Fox, formerly health officer of Buncombe County, has been made assistant director of county health work.

**Society News**—Drs Austin I. Dodson, Richmond, and Adolph Rumreich, Washington, D. C., addressed the summer meeting of the Third District Medical Society at Southport, July 27, on "Management of Prostatic Obstruction" and "Spotted Fever—Eastern Type and Typhus Fever," respectively. Dr Sylvia Allen, Charlotte, addressed the York County Medical Society, Rock Hill, July 27, on epilepsy. Dr Ernest O. Swartz, Cincinnati, addressed the Buncombe County Medical Society, Asheville, July 14, on "Carbuncle of the Kidney."

## OHIO

**Radium Stolen**—Dr Edward O. Bauer, Middletown, reported to police, August 1, that a package of radium valued at \$3,500 had been stolen from his automobile. Another package containing \$5,000 worth of radium was not disturbed, he said. The radium was the property of Dr Mabel E. Gardner, Middletown.

**Personal**—Dr Anthony R. Grierson, Sandusky, recently passed the state bar examination. Dr Frank R. Dew, Barnesville, has been appointed health officer of Lorain County, with headquarters at Oberlin. Dr Wilbert A. Hobbs, East Liverpool, was the guest of honor at a reception given by the Kiwanis Club of East Liverpool, July 19, celebrating his fiftieth anniversary in the practice of medicine.

## PENNSYLVANIA

**Society News**—The Westmoreland County Medical Society held its annual welfare meeting at the Torrance State Hospital, August 16. A symposium on psychiatric problems in the community was presented by Dr Josephine Funderburgh, Mr. E. M. L. Burchard, staff psychologist, and Miss Ray Blight, staff social worker. Dr John I. Wiseman, Mayview, clinical director, spoke on "Hereditary and Environmental Factors in Mental Disease" and Miss Prudence Matter, staff dietitian, on "Food Problems in a Mental Hospital." Dr William S. Wheeling Windber, addressed the Cambria County Medical Society, Johnstown, August 9, on "Medical Economics and Medical Ethics in Their Relation to the Modern Hospital." Dr Olin G. A. Barker, Johnstown, showed motion pictures of Mexico and Yucatan.

**Regional Cancer Conference**—The cancer commission of the Medical Society of the State of Pennsylvania sponsored a regional meeting in Sayre, August 13. Speakers at the scientific session were:

- Dr Samuel J. Watervorth, Clearfield: Relation of Trauma to Cutaneous Malignancy
- Dr Lyndon H. Landon, Pittsburgh: Relation of Trauma of the Osseous System
- Dr Stanley P. Reimann, Philadelphia: Biologic Work on Growths
- Dr William Wayne Bahcock, Philadelphia: Breast Conditions and Their Relation to Malignancy
- Dr Charles C. Norris, Philadelphia: Significance of Menopausal Hemorrhage with Especial Reference to Carcinoma
- Dr Fred W. Rankin, Lexington, Ky.: Carcinoma of the Colon
- Dr Elmer Hess, Erie: Tumors of the Bladder

Drs Robert B. Greenough, Boston, and Dean Lewis, Baltimore, addressed a public meeting in the evening. Dr Jonathan M. Wainwright, Scranton, chairman of the cancer commission, who was to have appeared on the program, died August 3.

## Philadelphia

**Survey of Outpatients**—The Philadelphia County Medical Society recently sponsored a study of hospital outpatient departments, which was carried out in cooperation with the Joint Committee on Research of the Community Council of Philadelphia and the Pennsylvania School of Social Work. Nineteen hospitals furnished information concerning 1,036 patients. The questions to which answers were sought were as follows:

1. Do the outpatient departments of hospitals waste their resources in duplication of examination and treatment of patients who are merely shopping around?
2. Are the outpatient departments accepting patients who could afford to pay private physicians?
3. Could a medical registration bureau be made to pay for itself out of the savings in money which might be effected by elimination through clearing the names of patients and recording their financial status?

The survey showed that 272 patients, about one in every four of those investigated, were known to two or more hospitals. A special study of 104 of these showed that thirty-nine changed hospitals because they were dissatisfied with treatment, fifty-five for other reasons, such as moving from one district to another, in ten cases the reports were inadequate. Only about 5 per cent were considered "chronic shoppers." Of the 272 duplicating patients, less than 5 per cent were found to be able to pay any part of their expenses for medical care. 170 were on relief, 25 were dependent on relatives and friends, 47 had incomes insufficient to provide for medical care, 13 were considered able to pay reasonable charges, and in 17 cases the economic situation was not reported. Concerning the 764 patients whose names were found in only one hospital, it was ascertained only that they were costly patients to some hospital and that the proportion of them known to relief agencies (62.6 per cent) was almost identical with the rate among the 272 who were studied in detail (62.5 per cent). From this it was inferred that the economic status was in general the same in the two groups. The evidence gathered in this study indicated that the majority of these clinic patients had formerly been under the care of private physicians, whom they left when they felt they were unable to pay. The question concerning the establishment of a medical registration bureau could not be answered, the investigators declared. This phase of the study was not brought to a satisfactory conclusion chiefly because the hospital records and the hospital accounting methods were not adapted to supplying answers needed. There were no comparable data among the hospitals on costs of treatment to these patients the report said, therefore it was impossible to determine the costs of the duplications and there could be no definite answer to the possibility of financing a registration bureau out of savings.

## SOUTH CAROLINA

**Hookworm Survey**—The state department of health will begin a survey of hookworm in the state September 1, under the direction of Dr James A. Hayne, state health officer, and Dr Benjamin F. Wyman, Columbia, director of rural sanitation, newspapers report. Dr Alvin E. Keller, professor of preventive medicine and public health, Vanderbilt University Medical School, Nashville, Tenn., will assist in the survey and corrective campaign. Every county in which the disease is prevalent will be visited and the results checked with a survey made by the Rockefeller Foundation in 1914.

## WISCONSIN

**Subsidiary Board of Examiners**—The National Board of Medical Examiners recently organized a subsidiary board for part III, with Drs J. Gurney Taylor and Hjalmar T. Kristjanson, Milwaukee, as chairman and secretary, respectively.

**State Medical Meeting at Green Bay**—The ninety-third annual session of the State Medical Society of Wisconsin will be held in Green Bay, September 12-14. General meetings will be held each afternoon and the mornings will be occupied by dry clinics given by Green Bay physicians, clinical demonstrations and section meetings. Guest speakers will include:

- Dr James M. Hayes, Minneapolis: Prevention and Treatment of Complications Following Cholecystectomy
- Dr Gilbert J. Thomas, Minneapolis: Tuberculous Disease of the Kidney
- Dr Herman L. Kretschmer, Chicago: Prostatic Resection
- Dr Fred Jenner Hodges, Ann Arbor, Mich.: Diseases of the Colon
- Dr Leo G. Rigler, Minneapolis: Early Diagnosis of Carcinoma of the Stomach
- Dr Arthur W. Erskine, Cedar Rapids, Iowa: Carcinoma of the Breast
- Dr Harry E. Mock, Chicago: Skull Fractures
- Dr Loyal Davis, Chicago: Surgical Treatment of Trigeminal Neuralgia
- Dr Herbert Z. Giffin, Rochester: Summary of the Causes of Anemia with Fundamentals Concerning Treatment
- Dr Owen H. Wangenstein, Minneapolis: Diagnosis and Treatment of Acute Intestinal Obstruction
- Dr Ellis Fischel, St. Louis: Everyday Problems in the Diagnosis and Treatment of Cancer
- Dr Robert S. Dismore, Jr., Cleveland: Surgical Problems Associated with Cholelithiasis
- Dr George B. Eusterman, Rochester, Minn.: Management of Gastric Lesions
- Dr Edwin W. Ryerson, Chicago: Lesions of the Knee Joint
- Dr Dean Lewis, Baltimore: Difficulties in the Diagnosis of Tumors
- Dr Albert H. Montgomery, Chicago: Congenital Anomalies of the Gastrointestinal Tract
- Dr W. Russell MacAusland, Boston: Present Status of Arthroplasty in Ankylosed Joints
- Dr Edward Starr Judd, Rochester, Minn.: Prevention of Surgical Complications

At the annual dinner Thursday evening at the Northland Hotel, Drs. Lewis, Past President, and Olin West, Chicago, Secretary of the American Medical Association, will be the speakers. The annual golf tournament will be held Tuesday, September 11, at the Oneida Golf Club.

## GENERAL

**Society News**—The thirty-eighth annual conference of Dairy, Food and Drug Officials of the United States will be held, October 15-18.—The American Hospital Association will hold its annual meeting in Philadelphia, September 24-28

**Unauthorized Solicitor**—A physician of Logan County, Ill., reports that one A A Kennedy is visiting physicians and clergymen claiming to represent the P F Collier Distributing Corporation, Louisville, Ky., and that he collects \$10 deposits on orders for an encyclopedia. This firm states that the man was in its employ until May 1934 but now has no connection with it

**Automobile Fatalities in Four Weeks**—The bureau of the census, U S Department of Commerce, announced that eighty-six large cities in the United States reported 609 deaths from automobile accidents for the four weeks ended August 4, as compared with 601 deaths during the week ended Aug 5, 1933. Of the total number, 433 occurred within the corporate limits of cities. For the fifty-two week periods ended Aug 4, 1934, and Aug 5, 1933, the totals for all cities were respectively 8,706 and 7,880, which indicate a recent rate of 23.3 per hundred thousand of population as against an earlier rate of 21.1

**Bequests and Donations**—The following bequests and donations have been announced recently

Bryn Mawr Hospital Bryn Mawr Pa. a provisional bequest of \$20,000 from the will of Ellen W. Longstreth

Caledonia Hospital Brooklyn \$10,000 and half the residue of the estate valued at \$138,776 contingent on the death of two beneficiaries by the will of Donald G. C. Sinclair

Presbyterian and St. Luke's hospitals New York \$5,000 each by the will of Mrs. Florence Coe Stewart

Charles T. Miller Hospital St. Paul \$20,000 by the will of the late George H. Prince and an anonymous donation of \$5,000 toward its free bed fund

New York Orthopedic Hospital \$10,000 by the will of the late Mrs. Elizabeth Mills Reid

St. Raphael's Hospital New Haven Conn., \$10,000 to found the Alice Derby Lang Fund from the will of the late Prof. Henry R. Lang

**Changes in Status of Licensure**—The State Medical Board of Ohio reports the following action taken at its regular meeting in Columbus, July 12

License of Dr. Ruth Cassel Schweisberger Canton revoked following her conviction on a charge of criminal abortion. She is confined at the Marysville Reformatory for Women

The State Board of Health of Missouri reports the following action

The license of Dr. Clarence Alexander Wright to practice medicine in Missouri was revoked May 23 following his conviction on a charge of performing an illegal operation

The Missouri license of Dr. Joseph Moreau Blakemore at one time of Chicago was revoked May 23 by reason of the fact that his Illinois license had been revoked for professional connection with an unlicensed person. The Illinois revocation took place March 8, 1933

The New York State Board of Medical Examiners reports

The license of Dr. Louis Henry Pinco Yonkers which was suspended April 20, 1933 was restored April 20

**Fraudulent Solicitor**—It has been reported that a man giving the name R. E. Owens has been calling on hospital executives in Wisconsin claiming to represent *THE JOURNAL, Hospital Management* and "American and Canadian Hospitals," a directory published by the Midwest Publishers Company, Minneapolis. The hospital journal reports that the man is not known in that office. The Midwest Publishers Company writes that on July 19 a Mr. R. E. Owens appeared at that office, saying that he represented *THE JOURNAL* and *Hospital Management* and requesting that he be allowed to represent also "American and Canadian Hospitals." On the strength of these apparent connections, the man was allowed to take a copy of the latter publication for examination and was instructed to return later in the week. He did not return and the only address he gave was the Morrison Hotel, Chicago. It was said that he made an excellent appearance, was about 6 feet tall, and was slender and of medium coloring. He does not represent *THE JOURNAL*.

## CANADA

**Personal**—Dr. Wilder G. Penfield, clinical professor of neurological surgery, McGill University Faculty of Medicine, Montreal, received a ceremonial chalice at the twenty-first reunion of the class of 1913 of Princeton University, Princeton, N. J. June 15. The chalice has been dedicated by the class to commemorate outstanding accomplishments of its members and will be retained by Dr. Penfield until another award is made.—Dr. Robert A. H. MacKeen, assistant professor of pathology and bacteriology, Dalhousie University Faculty of Medicine Halifax Nova Scotia and assistant pathologist for the province, has been appointed director of the bureau of laboratories of New Brunswick to succeed the late Dr. Harry

L. Abramson.—Dr. Charles Ferdinand Martin, dean of McGill University Faculty of Medicine, Montreal, was awarded the honorary degree of doctor of laws by Harvard University at its recent commencement

**Society News**—Dr. Daniel S. Macnab, Calgary, was elected president of the Alberta Medical Association at the annual meeting in Calgary, June 22.—Dr. Donald C. Malcolm, St. John, was elected president of the New Brunswick Medical Society at the annual meeting in Woodstock, July 10-11. Among speakers were Drs. Frederic J. Cotton, Boston, on treatment of fractures and Rafe Nelson Hatt, Springfield, Mass., on diseases and injuries to the hip joint.—At the annual meeting of the Prince Edward Island Medical Association in Summerside, July 13, guest speakers were Dr. Jonathan C. Meakins and Dudley E. Ross, Montreal, on anemias and cleft palate, respectively. Dr. Victor L. Goodwill, Charlottetown, was elected president.—Dr. J. Preston Max, well professor of obstetrics and gynecology, Peiping Union Medical College, Peiping, China, addressed the Medical Arts Club of Winnipeg, July 13-17, on "Osteomalacia and Adult and Fetal Rickets."

## FOREIGN

**Personal**—Prof. Bernhard Zondek, former head of the gynecologic department of the Charity Hospital in Berlin, has been appointed to direct the obstetric and gynecologic departments of the Hadassah-Rothschild Hospital in Jerusalem

**International Congress on Tropical Medicine**—The ninth international congress of the Far Eastern Association of Tropical Medicine will be held in Nanking, China, October 1-7. This congress was originally set for October 1933. Official languages of the congress are English, French and German. Various sections will hold meetings on many aspects of tropical disease, with special attention to cholera, leprosy, yellow fever, plague and malaria. Section meetings will be held in the mornings and two afternoons, and the remainder of the afternoons will be devoted to visits to institutions. Information may be obtained from the secretary, Dr. P. Z. King, Wei Sheng Shu Nanking

## Government Services

## Sixth Annual Medicomilitary Symposium

The sixth annual inactive duty training course for medical reserve officers of the army and navy will be held at the Mayo Clinic, Rochester, Minn., October 7-20. Morning hours will be devoted to clinics on subjects selected by the student officers and afternoons to medicomilitary subjects. The general subject will be "Public Health and Its Relation to National Defense." The program will be under the direction of Col. Kent Nelson, U. S. Army, Seventh Corps Area Surgeon, Omaha, and Capt. John B. Mears, U. S. Navy District Medical Officer, Ninth Naval District Great Lakes, Ill., to either of whom application may be made. One hundred hours of credit will be given for the course, those who cannot remain for the entire time may join or leave at any time and will receive credit for the hours spent.

## Misabeled Beer to Be Seized

Beer so labeled as to lead buyers to believe that it has an unusually high alcoholic content will be seized and prosecution of the brewers will be started whenever such a product is found in interstate commerce, it was announced July 14. A brewery that makes a nationally distributed beer complained to the Food and Drug Administration that a New Orleans brewer has labeled beer that contains less than 4 per cent of alcohol in this manner. Does not contain more than 6 per cent of alcohol by volume," with the 6 per cent printed in large numerals. The administration pointed out that while it does not require a statement of alcoholic content on foods and beverages, it does require that food, including beer, shall not be labeled with any statement, design or device that is misleading in any way. Action has already been taken against a number of beers bearing misleading or ambiguous statements of alcoholic content, it was said. Cases were cited in which the alcoholic content was expressed in the form of degrees proof, such as "12 proof" with the figure 12 in large type and the word "proof" in inconspicuous letters. Few purchasers know that the percentage of alcohol by volume is only half the degrees proof, even if they notice the small and inconspicuous word "proof," it was said.

### LONDON

(From Our Regular Correspondent)

July 28, 1934

#### Annual Meeting of British Medical Association

Two thousand physicians attended the one hundred and second annual meeting of the British Medical Association, which was held at Bournemouth. At the representative meeting a number of important medicopolitical subjects were discussed.

#### RESEARCH SCHOLARSHIPS AND GRANTS

Sir Ewen J Maclean proposed an increase in the amount allocated to research scholarships and grants. A powerful, rich association, such as theirs, was giving only \$5,000 a year for research. Much money was wasted under the blessed name of research but there was no waste of the money devoted by the association to research. The treasurer, Mr N Bishop Harman, said that the income of the association was \$780,000, and careful analysis showed that the items of expenditure that could legitimately be regarded as expended directly in the advancement of science totaled \$350,000. While sympathizing with the motion he pointed out that, with the government grants and so many associations willing in some cases too willing, to give money for research, it was not necessary for the association to go further. It was far better to disseminate the knowledge of medical science among its members. The motion was defeated.

#### MEDICAL EDUCATION

Sir Henry Britten Brackenbury, chairman of the Committee on Medical Education, presented for approval a report that had previously been circulated. Its main provisions were that the opportunity had arisen and should be taken advantage of to raise the general standard of education and the standard of scientific education for those about to enter the medical profession, that the course of the curriculum should be considered as a whole, that there should be no isolated departments acting separately from one another but that the whole course of instruction should be coordinated first, in emphasizing the preventive aspects of medicine and, secondly, in emphasizing that the human personality is a whole and that attention should be paid not merely to a disease process going on inside the human body as a vehicle but to a human person who desired to be made well, and that in the latter part of the curriculum there should be a period when the student, before he started out as a registered physician, should be given as much responsibility as possible under supervision. An amendment to qualify the recommendation by deleting any reference to general approval, so that the resolution simply read that the report be sent to the various bodies mentioned, was carried.

#### OVERCROWDING OF THE PROFESSION

Dr Arnold Gregory moved the raising of the age of registration of medical students to 18 years, a point on which the teaching profession was unanimous. At present the average student was too young and immature and his general education had not reached the standard to enable him to obtain full benefit from his medical education. Further, the rise in the general standard of education among the general population since the war called for a higher standard in those entering medicine. The number of students was growing steadily year by year and now taxed the capacities of the schools. Further, the profession had reached the saturation point and as in all civilized countries, the time had come to limit its numbers. At the end of 1932 there were more than 56,000 names on the Medical Register, 10,000 more than in 1922 and 19,000 more

than in 1902. The population had not increased in anything like the same proportion. Considerable sympathy was expressed with the resolution, but technical objections were raised and it was withdrawn.

#### RECOGNITION OF CHIROPODISTS DEFEATED

A recommendation of the council was presented that the medical profession should accord a measure of recognition to approved chiropodists who accept the definition of their work that "chiropody means the treatment of abnormal nails and all superficial excrescences occurring on the feet, such as corns, warts, callosities and bunions," and who undertake to confine their practice to this field and not even within it to operate on any congenital or acquired deformity, any condition requiring a general anesthetic, or any condition involving any structure below the level of the true skin, or to treat any patient under the care of a physician without his knowledge and consent. Dr Langdon-Down, who moved the resolution, described chiropodists as an ancient confraternity giving a service accepted (if silently) by the medical profession and appreciated by the public. Their restricted field was not cultivated by the profession. Of recent years the public had tended more and more to resort to chiropodists, whose methods had developed, and institutions, such as foot hospitals and foot clinics, were being widely established. Associated with this was extension of the courses of training, in which the medical profession had assisted. If the profession stood aloof it would lose the power of directing and limiting the development of this speciality. Dr C O Hawthorne opposed the motion. Chiropody was either an esthetic enterprise or a therapeutic measure. If the former, the medical profession had no more concern with it than with manicure or hair dressing, if the latter, diagnosis must precede treatment, and the minimum training for diagnosis was the medical curriculum. The medical profession should not associate itself in any way with a group of unqualified practitioners. This implied no animosity on the part of the profession but only that the responsibility of taking such advice rested on the patient. The Council's recommendation was rejected by 102 votes to 65.

#### Cooperation Between Medical Schools and Municipal Hospitals

The municipal hospitals are now equipped on the most modern lines and have a part time staff of consultants drawn from the voluntary hospitals. Plans for a still greater cooperation have now been arranged. The medical schools of London number twelve and have grown rapidly in the last 150 years. They originated in a system of apprenticeship, under which the students became apprentices to the individual members of the staffs. Later this system was terminated and the modern medical schools were established. Early in the present century these schools became constituent colleges of the London University. The range of medical education has now become so wide and the subjects of training for a physician so complex that the problems of teaching are becoming more and more difficult. To meet this difficulty, cooperation with the municipal hospitals has been arranged. An executive council consisting of the dean and four members of the teaching staff of each school has been formed and subjects of educational importance will be discussed throughout the year. Certain courses of study are being organized for which it is difficult to cater in an individual medical school but which can be arranged without difficulty for the students of more than one school. The students of each school will be permitted under an arranged scheme to avail themselves of the clinical facilities of other schools. In order to allow the scheme to develop gradually, the arrangements for an interchange of clinical teaching will be confined at first to St Bartholomew's and St Thomas's hospitals. After the preliminary experience, when the organiza-

tion has become stabilized, similar facilities will be extended to Guy's. It is hoped that this cooperation will be of great benefit to medical education. Under arrangements now made between the London Voluntary Hospitals Committee and the Hospitals and Medical Services Committee of the London County Council, each medical school is linked with a municipal hospital in its neighborhood. The arrangements provide for clinical demonstrations at the linked hospitals. Special facilities have been provided for instruction in obstetrics. Students of voluntary hospitals are now enabled to reside for a fortnight at municipal hospitals, during which approximately ten cases are allotted to each. It is thought that sooner or later there must be closer approximation of the two classes of hospital, so as to make the best use of the 96,000 beds now available in London.

#### Memorial to Sir Robert Jones

An appeal for a national memorial to Sir Robert Jones, who is claimed to be "the creator of modern orthopedic surgery," was made at the Mansion House under the presidency of the lord mayor of London. It is proposed that the memorial shall comprise a Robert Jones professorship in the Royal College of Surgeons, a Robert Jones traveling fellowship, to be awarded alternately by the Royal College of Surgeons and the University of Liverpool (the city in which Jones practiced) and the Liverpool Medical Institution. Rudyard Kipling, who was to have spoken, was unavoidably prevented from attending. Lord Moynehan said that the gifts of Robert Jones to the science and art of surgery had rendered his name immortal. Immortality attached only to the things of the spirit, and it was the gifts of Robert Jones to the spirit of surgery that the memorial was designed to commemorate. He was one of the two great scientific heroes of the war, and it was the baldest truth to say that hundreds of thousands of men owed not only their recovery but their restitution to physical health directly to his skill. But the great thing about a surgeon was not his immediate work but the lessons that he gave, the craft that he taught, the spirit that he inspired in those who came after. The lessons taught by Jones throughout the war were now part of the heritage of surgeons throughout the world. In the name of his colleagues across the Atlantic, Lord Moynehan could say that they would ever bear the name of Jones in proudest remembrance.

#### Local Anesthesia Applied to the Stellate Ganglion

Professor Leriche of Strasbourg has just completed a research on the effects of anesthesia applied directly to the stellate ganglion. The patient is placed on a horizontal table with pillow under the neck and the head turned away from the operator. Starting with the middle of the clavicle, the upper margin of that bone is shaven and a pliable platinum needle, from 8 to 10 cm. in length and 0.6 mm. in diameter, is inserted in the direction of the transverse process of the seventh cervical vertebra. Contact with the bone having been obtained, a double movement is given to the needle. The large end of the needle is raised so that the point drops down the width of one vertebra, while, at the same time, the needle is directed 30 degrees outward. At this moment the needle is in contact with the stellate ganglion. The injection of 10 cc. of procaine hydrochloride (1 per cent solution) is sufficient to induce anesthesia of the ganglion. Technical errors would consist in puncturing the subclavian or the vertebral artery or in penetrating the cerebral space. That would cause no great harm, and the error would be evidenced by the passage of a drop of blood or of cerebrospinal fluid through the needle after its introduction. The danger of wounding the apex of a lung is

more serious, for then pneumothorax would follow. The injection is followed immediately by a marked facial vasodilatation, but this lasts only a few minutes. This method is useful in diagnosis and treatment. If one is planning to extirpate the stellate ganglion in treating angina pectoris or asthma, and this anesthesia effects no improvement, even momentary, this is evidence that it is of no use to extirpate the ganglion. If, however, a good result is secured, this indicates that the operation will offer good chances of recovery. Leriche has observed several cases of asthma in which anesthesia of the stellate ganglion brought about improvement, and in some cases several repetitions of this anesthesia brought about a consistent recovery after a few days of treatment. Excellent results were secured in allaying pain in the stump following amputations of the arm. There is an advantage in combining therewith anesthesia of the second thoracic ganglion by the dorsal route. A curious feature is that, in algias of the arm, one secures permanent effects although the action of the anesthetic may be only momentary. Leriche declares that while the fact cannot be questioned, the mechanism is difficult to explain.

#### Retarded Contractions of the Iris in Mental Patients

Mr. Andre Barre, physician of the urologic clinic of the Hopital de la Salpetriere, has announced a clinical sign that, he contends, aids in the diagnosis and the prognosis of various mental disorders. The sign consists in noting slight contractions in the iris, at the end of several moments of observation. In a normal person these slight oscillations of the margin of the iris are seen at the end of from ten to sixteen seconds (sometimes thirty seconds) in aged persons or in persons presenting natural mydriasis. When the oscillations begin to manifest themselves, there are usually from twelve to nineteen in two minutes, with an average of fourteen, this figure being never lower nor higher in a subject who is entirely normal. The manifestation that indicates serious mental disorder lies in the slowness with which these oscillations begin and in the reduction of their number—which may end in their complete suppression. It appears that the figures given for a normal subject correspond to a normal and well balanced mental activity. Barre has applied this method of examination to a large number of different mental states. In idiots the oscillations, as a rule, do not exist, even after a prolonged period of observation. The exceptions are rare. In imbecility there is a marked retardation for the onset of the contractions of the iris, a retardation exceeding a minute and a half and sometimes going to three minutes. As to the number of oscillations that may be counted in two minutes, they are not only very weak but also wide apart—about four on an average. In states of mental debility, the contractions of the iris do not begin until after one minute and sometimes more than two minutes. Moreover (an important fact), the subjects in whom the retardation was the most marked were those who, at the start, presented simple weakness but who developed later definitive types of dementia. This sign appears to have, therefore, considerable prognostic value. The author, after observations made on aged persons of the same age, who were normal, concluded that the sign is independent of age and may be elicited only in case of dementia. In cases of dementia praecox, hebephrenia, catatonia and schizophrenia, one observes without exception retardation of the contractions of the iris. The interval is never less than thirty-five seconds and may reach three to five minutes or even longer. The contractions may be entirely absent. These contractions when they exist are extremely weak and wide apart—of a trembling nature and scarcely perceptible. The retardation appears to be proportioned to the gravity of the mental state. Remissions and ameliorations are associated with any return of the contractions of the iris to a normal state. Hallucinatory and convulsive states furnished similar results. In

melancholia there is a definite relation between the indications furnished by this symptom and the mental state of the subject—the symptom improves parallel with any improvement in the mental state. In dementia paralytica, in addition to the usual signs supplied by an examination of the accommodation of the pupil, the iris is absolutely motionless. The author wisely says that this sign must not be regarded as pathognomonic and one that will be of great aid in psychiatric diagnosis, for it is observed in widely different conditions and, exceptionally, it may give false information. Nevertheless, he emphasizes the prognostic value of the sign. It may furnish valuable information on the chances of amelioration or aggravation of the patient's condition, aside from the confirmation of a purely psychiatric order.

### Number of Physicians in German Cities

The statistical department of the German Medical Organization has just published a report on the distribution of practicing physicians throughout the cities of Germany, and some of the details follow.

Classified Cities	Total Population of Group	Number of Practicing Physicians	General Practitioners	Specialists	Per centage of Specialists
1 59 large cities (more than 100,000 pop.)	19,782,000	18,007	9,610	8,397	46.6
2 49 cities (50,000-100,000 pop.)	3,578,300	2,902	1,432	1,470	50.7
3 158 cities (10,000-50,000 pop.)	4,804,600	3,725	1,993	1,732	46.5
4 240 cities (10,000-100,000 pop.)	3,589,000	2,469	1,740	729	29.5
Totals 529 cities	31,763,800	24,103	14,775	12,328	49.5

Of the 39,000 practicing physicians in Germany, there are more than 27,000 in the cities with more than 10,000 population. It is evident that 48.7 per cent of the total population of Germany has 59.5 per cent of the practicing physicians.

Comparing this with the last census of the kind, taken in 1932 (*THE JOURNAL*, July 8, 1933, p. 152), it will be seen that scarcely any shifting has occurred in the relation between the number of physicians and the number of cities comprised in the four groups, although there are 700 fewer physicians in these groups, which is doubtless due to recent political regulations.

The first group (large cities), with 30.3 per cent of the total population, comprises 46.2 per cent of the total number of practitioners. Of these 18,000 physicians, only 13,355 have been admitted to panel practice.

Scrutiny of the table leads to the conclusion that the hesitation about settling in rural districts is gradually disappearing. In 529 cities the number of specialists, as compared with 1932, has decreased by 144, although, considering the percentages, there are no essential differences in the various groups of specialists as against 1932. The number of gynecologists, internists, orthopedists and roentgenologists has increased slightly, while the representation in the other groups of specialists has declined somewhat. The percentage of gynecologists falls rapidly with the relative size of the various groups of cities, there being 12.9 per cent in group 1, as compared with 8.0 per cent in group 4. On the other hand, the percentage of specialists in surgery and diseases of women rises from group 1 up to group 4 (2.4, 4.8, 7.4 and 17.0 per cent). The dermatologists show a decline from 15.6 per cent in group 1 to 5.6 per cent in group 4. The internists show no marked decrease until the smaller cities are reached. The percentages for groups 1

to 4 are 15.7, 15.6, 16.2 and 11.9. In the cities of groups 1 and 2 the internists have the strongest representation among the specialists. The distribution of the pediatricians is similar, although they have the strongest representation in group 3. Among the ophthalmologists and the otorhinolaryngologists the usual observation is made that the representation is strongest in the smallest towns.

The panel physicians (*kassenärzte*) show an increase of 677 in the 529 cities included in this survey, whereas the number of physicians permanently located shows a decline of 742, although it should be mentioned that the number of cities surveyed is somewhat larger than in 1932. At that time the total number of panel physicians in the whole Reich was 32,000, the number today is 31,847. In spite of the preference shown physicians who took part in the war, the total number of panel physicians has not increased, because about 1,500 non-Aryans and communists have been excluded from panel practice. Of the 31,847 panel physicians now enrolled, 21,091 are located in the 529 cities, with the following distribution: group 1, 13,355 panel physicians, 47.3 per cent of whom are specialists; group 2, 2,316, 48.4 per cent specialists; group 3, 3,166, 44.4 per cent specialists; and group 4, 2,254, 28.1 per cent specialists.

The "large cities" claim 41.7 of the total number of panel physicians. The percentage of specialists is somewhat smaller among the panel physicians than among the physicians settled in a permanent abode (44.9 as against 45.5 per cent). The highest percentage is found among the otorhinolaryngologists, neurologists, ophthalmologists, dermatologists and gynecologists, the percentage having risen in a number of the specialties, for example, as to the gynecologists, internists, neurologists, pediatricians, orthopedists and roentgenologists. Of the additional 677 panel physicians, 588 are specialists and only 89 are general practitioners. In the distribution of the specialists among the panel physicians according to city groups, the same observations may be made as among the specialists in general.

### Convalescents' Serum in Acute Anterior Poliomyelitis

In an article in the *Klinische Wochenschrift*, Schlossberger and Krumeich of the federal bureau of health state that it was eminently desirable that observations on the effects of administering convalescents' serum in poliomyelitis be collected. The outbreak of 1932 offered such an opportunity, particularly as special arrangements were perfected for the preparation of convalescents' serum (*THE JOURNAL*, Oct. 21, 1933, p. 1327). To secure a survey of the results, a special session of the federal health council, to which numerous experts were summoned, was called. In addition, the federal bureau of health sent questionnaires to all physicians and hospitals that had ordered convalescents' serum. Exact clinical reports on 227 cases were received. Patients with uncertain diagnosis were excluded. Of these 227 patients, twenty-six were given the serum in the preparalytic stage and 201 after the appearance of paralysis. In the twenty-six patients, a complete cure of the disease without paralysis was effected. There were no deaths, although in two patients of this group paralysis developed later. In contrast with the results just mentioned, the disease proved fatal in twenty-five of the 201 patients of the second group. According to the observations of the attending physicians, in 148 of these 201 patients the administration of serum had no influence on the paralysis, while in the remaining twenty-eight cases there was a pronounced retrogression of the paralysis. But since such improvement was observable with about the same frequency also in untreated patients, no special importance can be attached to these observations. The view expressed by many other physicians must be endorsed, namely, that convalescents' serum will not bring about a retrogression of paralysis once it has developed. Since the

number of patients who died, although treated in the paralytic stage with convalescents' serum, corresponded closely with the mortality that prevailed in 1932, it does not seem likely that the administration of the serum after the onset of paralysis exerted any harmful effect. The conclusion is, therefore, that convalescents' serum may be injected after the onset of the paralytic stage with a view to checking, if possible, the progress of paralysis.

Although the number of patients in Germany treated with convalescents' serum in the preparalytic stage is too small to justify a final opinion, the observations made thus far seem to show that this therapeutic measure has proved its high value. Great care must be taken therefore, by the creation of a suitable organization, that cases of poliomyelitis are recognized promptly and that serum treatment is instituted in season.

#### Decline of Infant Mortality

In 1933, infant mortality showed a decline. There were 45,279 deaths of children during the first year of life, as compared with 47,948 deaths in 1932 and 53,177 deaths in 1931. In 1933 there were 76 deaths per thousand, as against 80 in 1932, 84 in 1931, 104 in 1925 and 150 in 1913. Nevertheless the excess of births over deaths for Prussia in 1933 was only 144,022, which is 34,566 fewer than in 1932 and 49,880 fewer than in 1931. The excess of births over deaths amounted in 1933 to 3.5 per thousand of population as against 4.5 in 1932 and 4.9 per thousand in 1931. In 1925 the excess of births over deaths was 9.1 per thousand, and in 1913 13.3 per thousand of population.

#### The Detection of Tuberculous Persons

According to the statements of Dr. Hoth, about one fifth of all recognized cases of open pulmonary tuberculosis and more than half of the cases of closed pulmonary tuberculosis in Bremen were detected by the tuberculosis consultation center. Among these patients who were first discovered by the care-taking center there were comparatively more cases of recent origin than among the patients notified to the care-taking center from outside sources of information. It has been the experience of the Bremen care-taking center that not only the initial examination of the entourage of patients with open tuberculosis but also the continued observation of persons found on the first examination to be uninfected led to the detection of a considerable number of patients with lung involvement. It has been shown that in Bremen through the continued observation of healthy persons, just as many cases of open and of closed tuberculosis have been discovered as with the aid of the most successful serial examinations.

#### Protein Requirements

From numerous experiments on nitrogen balance and from the study of freely chosen protein-rich and protein-poor diets Dr. W. Heupke of Frankfurt-on-Main has drawn the following conclusions. In most diets the protein minimum lies between 30 and 40 Gm. Hundreds of millions of human beings cover their protein requirements by the ingestion of a protein intake ranging between 50 and 70 Gm, which conserves bodily performance. Hence a protein intake of 80 Gm must be regarded as amply sufficient. No disorders can be mentioned that are known with certainty to be due solely to a low protein intake. There are no diets freely chosen, and made up with any degree of reason, in which the protein intake was below the minimum requirements. The notion of a protein optimum appears superfluous, as dietitians are not in a position to assume that a certain number of grams of protein constitutes the most suitable intake. There is a wide range between an adequate protein intake and an excessive protein intake. In a short range of observation no injuries to health can be shown to be caused by the ingestion of an excessively large protein intake, but a

long range of observation furnishes evidence that an unduly large protein intake should be avoided, since modern research has shown that a high protein intake continued over a long period may give rise to disorders.

#### BUDAPEST

July 23, 1934

#### The Medical Congress at Balatonfured

The Congress of Internists was held at Balatonfured, a watering place on the shores of Lake Balaton. It was attended by a great number of physicians. The congress continued for five days and then the members went on excursions on the lake, which is fringed with resorts in glorious scenic settings.

#### TONSIL OPERATIONS ON CARDIAC PATIENTS

Dr. Vidor Zimonyi said that tonsil operations performed on account of endocarditis complicating tonsillitis are often attended with untoward results. The diminished defensive power of the organism may be shown by calculating the bactericide index. One may determine the time to operate by this diagnostic method. The normal index is between 50 and 55, which means that the organism is in a positive defensive phase. When this index number prevails, complications after operations on the tonsils may be averted. If the bactericide index is lower when the patient presents himself for operation he is in a negative defensive phase, a postoperative complication is to be feared, and the operation should be postponed.

#### "ALLERGIC" CHARACTER OF MIGRAINE

Dr. Bela Fornet, with his assistants, made extensive investigations into the cause of migraine and came to the conclusion that most cases show a decided "allergic" character. In its origin, an important factor is the constitution.

#### PROPHYLAXIS AGAINST DIPHTHERIA

Dr. Bela Keseru declared that the most efficacious method of protection against diphtheria is immunization with the Ramon anatoxin, which has proved to render 90 per cent of those inoculated immune. The protection, according to the statements of competent foreign authors, lasts for at least four or five years. In the county of Balatonfured immunization with the Ramon anatoxin has been made compulsory. In 1931, 2,922 children were given anatoxin three times. The result is that during the three years that has elapsed only one of the inoculated children has contracted diphtheria, and that case was very mild.

#### VITAMIN RESEARCH IN PEDIATRICS

Dr. Joseph Duzar, a university professor, has found that the feeding of infants with cow's milk is fraught with danger, owing to the lack of vitamins of the milk, brought about not only by repeated cooking and pasteurization but also by the feeding of cows in winter with fodder. The overfeeding with such milk infants with certain ailments brings on relative starvation, that is hypovitaminosis. The younger the infant the greater its relative vitamin need and the more the vitamin loss, with corresponding increase in susceptibility to fevers. The manifest severe avitaminoses in infants are rickets and certain eye conditions. More frequent are the latent avitaminoses, which also occur in babies nursed by mothers who exist on foods lacking in fats. Also one often encounters babies overfed with farinaceous foods. In such cases there is retardation of growth, loss of appetite, edematous obesity and a tendency to catarrhal feverish disturbances. Modern pediatrics regards it as its duty to feed these delicate and emaciated babies with foods containing an adequate quantity of vitamins. Vitamin research has shed a new light on the many-sidedness of the value of mother's milk, the food that is best adapted to the infant organism.

## Marriages

- WILLIAM J ELLIS, Covington, Va., to Miss Bessie Virginia Withrow of Clifton Forge, June 8  
ISAAC AVERY PHIFER JR., Buffalo, N Y, to Miss Marilou Hamilton of Asheville, N C., July 18  
WILLIAM E MITCHELL, Atlanta, Ga., to Mrs Helen Crockett of Ventura, Calif., June 12  
EUSTACE G HESTER, Saginaw, Mich., to Miss Anna Pope Bland of Shelbyville, Ky., July 7  
HARVEY N MIDDLETON, Anderson, Ind., to Mrs Stella Walker of Indianapolis, June 16  
JOHN DE WITT MORLEY to Miss Genevieve E Wager, both of Ashtabula, Ohio June 14  
ROYAL M MONTGOMERY, New York, to Miss Maxine Cooley of Denver, June 9  
WILLIAM B MATTHEW, Gary, Ind., to Miss Ruth Adams of Indianapolis, June 2  
JOHN H GLINN to Miss Eleanor C Schmidt, both of Chicago, June 18

## Deaths

Rudolf Bolling Teusler, Tokyo, Japan, Medical College of Virginia, Richmond, 1894, Associate Fellow of the American Medical Association, assistant professor of pathology and bacteriology at his alma mater, 1896-1900, in 1903-1904 Associated Press correspondent in Japan, member of the commission to provide postgraduate medical training in the United States for Japanese students, headed the American Red Cross mission which accompanied the American Expeditionary Forces to Siberia in the World War, since 1918 honorary physician to the American Embassy in Tokyo and from 1909-1912 he was physician to the British Embassy in Tokyo founder and since 1900 director of St Luke's International Hospital, Tokyo, and since 1925 director of St Barnabas' Hospital, Osaka, aged 58, died, August 10

Robert Hill Davis, University, Va., University of Virginia Department of Medicine, Charlottesville, 1901, member of the Missouri State Medical Association, professor emeritus of dermatology, St Louis University School of Medicine formerly dermatologist to the Jewish, St Anthony's and Bethesda hospitals, St Louis visiting dermatologist to St Louis City and the Barnard Skin and Cancer hospitals, St Louis, aged 58, died, June 19

Jonathan Mayhew Wainwright @ Scranton, Pa., Columbia University College of Physicians and Surgeons, New York, 1899, secretary of the American Society for the Control of Cancer, member of the American Surgical Association and fellow of the American College of Surgeons, veteran of the Spanish-American and World wars surgeon in chief of the Moses Taylor Hospital, aged 60, died, August 3, of carcinoma

Herbert Eliot Herrin @ Boston, Tufts College Medical School, Boston, 1910 member of the American Psychiatric Association and the New England Society of Psychiatry, acting medical superintendent of the Boston State Hospital, aged 51, died suddenly, July 15, of cerebral embolism, on the S S Somerset while on his vacation, just before the boat reached Baltimore

John Berton Carnett @ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1899, professor of surgery, University of Pennsylvania Graduate School of Medicine, served during the World War, member of the Associated Anesthetists of the United States and Canada aged 57, on the staff of the Graduate Hospital, where he died, July 29, of pneumonia

Harry Stober Carmany, Philadelphia University of Pennsylvania School of Medicine, Philadelphia, 1893, fellow of the American College of Surgeons, served during the World War aged 66, formerly associate surgeon to the Episcopal Hospital and visiting surgeon to the Memorial Hospital, where he died, July 14, of carcinoma

Isador David Bronfin @ Denver, Long Island College Hospital, Brooklyn, 1911, assistant professor of medicine in the department of tuberculosis, University of Colorado School of Medicine, fellow of the American College of Physicians, medical director of the National Jewish Hospital, aged 47, died, July 31, of tuberculosis

William Henry Johnson, Charleston, S C, University of Virginia Department of Medicine, Charlottesville, 1893, member of the South Carolina Medical Association, professor of orthopedics, Medical College of the State of South Carolina, on the staff of the Roper Hospital, aged 63, died, April 14, of heart disease

Bradford Frankfort Clutter, Borger, Texas, University of Louisville (Ky.) School of Medicine, 1906, member of the State Medical Association of Texas, past president of the Hutchinson County Medical Society, aged 53, died, April 27, in a hospital at Hines, Ill., of papillomatosis of the bladder

Othello Morino Bourland, Van Buren, Ark., Vanderbilt University School of Medicine, Nashville, Tenn., 1881, Bellevue Hospital Medical College, New York, 1883, member of the Arkansas Medical Society, aged 75, died, June 28, of coronary thrombosis

Ivan Isaac Yoder @ Cleveland, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1904, served during the World War, on the staff of the Lutheran Hospital, aged 58, died suddenly, July 12, of heart disease

Jeremiah Francis Crowley, Adams, Mass., Baltimore Medical College, 1894, member of the Massachusetts Medical Society, on the staff of the Plunkett Memorial Hospital, aged 62, died, July 4, of illuminating gas poisoning, self administered

Damon Alonzo Brown, Madison, Wis., Washington University School of Medicine, St Louis 1915, member of the American Urological Association, aged 44, died, May 14, in the Madison General Hospital, of streptococcal endocarditis

Ossip Wanshenk, New York, University of Kharkov, Russia, 1894, member of the Medical Society of the State of New York, aged 60 died, April 20, in the Mount Sinai Hospital, of lobar pneumonia, arteriosclerosis and heart disease

William Folsom Spaulding @ Greeley, Colo., Rush Medical College, Chicago, 1902, past president and secretary of the Weld County Medical Society, on the staff of the Greeley Hospital, aged 58, died, June 26, of coronary thrombosis

Walter Baylor Evans-Lombe @ Boise, Idaho, Northwestern University Medical School, Chicago, 1931, on the staff of the Idaho State Soldiers' Home Hospital, aged 33, was killed, June 30, in an automobile accident

George Simenton, Pontiac, Mich., Victoria University Medical Department, Coburg, Ont., Canada, 1885, member of the Michigan State Medical Society, aged 72, died, May 19, of carcinoma of the stomach

Eugene Nesbit Gatlin, Brookshire, Texas, University of Arkansas School of Medicine, Little Rock, 1888, member of the State Medical Association of Texas, aged 73, died, March 25, of cerebral hemorrhage

Lincoln Ellsworth Kidder, State College, Pa., Jefferson Medical College of Philadelphia, 1896, member of the Medical Society of the State of Pennsylvania, aged 69, died, June 3, of cardiac decompensation

Walter Fisk Boggess @ Louisville, Ky., Louisville Medical College, 1885, professor of medicine and clinical medicine, University of Louisville School of Medicine, aged 71, died, July 1, of heart disease

David Fuller Bentley, Camden, N J., Medico-Chirurgical College of Philadelphia, 1904, formerly county coroner, aged 74, died, June 25, in Miami, Fla., of coronary thrombosis and arteriosclerosis

William H Aikman @ Natchez, Miss., Tulane University of Louisiana Medical Department, New Orleans, 1885, aged 74, died, June 30, of nephritis, chronic encephalitis and Parkinson's disease

Benjamin F Tarver, Star City, Ark., University of Louisville (Ky.) School of Medicine, 1891, member of the Arkansas Medical Society, aged 70, died, June 20, of cerebral hemorrhage

Elisha Gregory, Mont Belvieu, Texas (licensed in Texas under the Act of 1907), member of the State Medical Association of Texas, aged 56, died, April 9, in Houston, of lobar pneumonia

Philip George Biddle, Dushore, Pa., Jefferson Medical College of Philadelphia, 1897, member of the Medical Society of the State of Pennsylvania, aged 67, died, May 21, of carcinoma

Jose Escabi, Mayaguez, P R., Harvard University Medical School, Boston, 1921, member of the Medical Association of Puerto Rico, aged 50, died, April 15, of uremia and acute nephritis

Callie Brown Charlton, Portland, Ore, Willamette University Medical Department, Salem, 1879, Hahnemann Medical College and Hospital, Chicago, 1886, aged 84, died, April 22

Abraham Epstein, Philadelphia, Medico Chirurgical College of Philadelphia, 1910, aged 48, died, June 24, in the Temple University Hospital, of carcinoma of the rectosigmoid

Albert W Lindbohm, Erwin, Mich, Saginaw (Mich) Valley Medical College, 1900, member of the Michigan State Medical Society, aged 64, died, March 18, of acute myocarditis

J Baptist Butts, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898, aged 83, died, March 18, of chronic nephritis

James Jefferson Johnson, Sulphur Springs, Texas, Memphis (Tenn) Hospital Medical College, 1897, served during the World War, aged 57, died, March 3, of heart disease

Amos D Gray, Chillicothe, Mo, Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901, aged 69, died, in February, of carcinoma of the stomach

Leonidas T Brown, Kansas City, Mo, Ensworth Medical College, St Joseph, 1893, aged 64, died, January 28, in St Luke's Hospital, of cerebral hemorrhage

Alfred L Fein, Chicago, Loyola University School of Medicine, Chicago, 1917, aged 46, died, July 18, of carcinoma of the lung with metastasis to the brain

Joseph L Nicholson, Haddonfield, N J, University of Pennsylvania School of Medicine, Philadelphia, 1890, aged 78, died, March 15, of chronic myocarditis

Elias Bibby, Milwaukee, University of the City of New York Medical Department, 1889, aged 65, died, July 4, of carcinoma of the thyroid gland

Yamei Kin, Peiping, China, Woman's Medical College of the New York Infirmary for Women and Children, New York, 1885, aged 70, died, March 5

John Edward Pope, Zama, Miss, Memphis (Tenn) Hospital Medical College, 1913, aged 49, was found dead, April 1, of a self-inflicted bullet wound

M L Johnson, West Point, Tenn, University of Tennessee Medical Department, Nashville, 1901, aged 66, died, March 29, of tuberculosis

Thomas Rickett Pooley Jr, Newton, N J, Cornell University Medical College, New York, 1907, aged 48, died, July 5, of pneumonia

Frederick Eugene Vrooman, St Francis, Minn, Kentucky School of Medicine, 1902, aged 61, died, June 25, of cerebral hemorrhage

James Clifton Gantt, Pulaski, Tenn, Meharry Medical College, Nashville, 1910, aged 53, died, April 25, in the Hale Hospital, Nashville

Isaac Sher, Chicago, Illinois Medical College, Chicago, 1901, aged 78, died, July 25, of myocarditis, nephritis and arteriosclerosis

Norman Francis Jacob, Kent, Ohio, Michigan College of Medicine and Surgery, Detroit, 1900, aged 61, died, in May, of heart disease

Mark Cyrus Gaines, New Orleans, Bennett Medical College, Chicago, 1913, aged 50, died, February 24, of cerebral hemorrhage

Walter R Barnes, Quincy, Mass, University of Vermont College of Medicine, Burlington, 1882, aged 79, died, January 18

Henry C Walbeck Jr, Louisville, Ky, Kentucky School of Medicine, Louisville, 1905, aged 56, died, June 1, of heart disease

Benjamin C Morgan, Fort Worth Texas, Atlanta (Ga) Medical College, 1884, aged 75, died, January 31, of pernicious anemia

Henry Thompson Burnap, Alton, Ill, St Louis Medical College, 1878, aged 78, died, July 3, of heart disease

James George Ross, Embro, Ont, Canada Rush Medical College, Chicago, 1900, aged 65, died, May 13

Frank Mulford Hill, Eastman, Ga, Meharry Medical College, Nashville, 1914, aged 49, died, April 25

William R Keeney, Tecumseh, Mich (licensed in Iowa in 1886), aged 86, died, March 24, of influenza

Fred Lyman Lewis, Cleveland, Cleveland Medical College, 1896, aged 60, died, in January

## Correspondence

### McCOY NO LONGER WITH LOS ANGELES TIMES

*To the Editor*—An anonymous letter received today enclosed a clipping from THE JOURNAL published by the American Medical Association under date of Aug 4, 1934, Vol 103, No 5, carrying an article headed "A Dietary Quack Discusses Dysentery," in which it is stated that Dr Frank McCoy of Los Angeles is associated with the Los Angeles Times as writer of a health column. I wish to correct this impression. Dr Frank McCoy has not been with the Los Angeles Times since February 1932.

E TAGGART,  
Secretary to L D HOTCHKISS,  
Acting Managing Editor

### DANGER IN ADMINISTRATION OF HUMAN SERUM

*To the Editor*—In THE JOURNAL, July 21, page 192, appeared a current comment treating with the administration of human serum and advising caution in its administration. The article made reference to a recent California case that cost the life of a young boy. A footnote stated that the tragedy was occasioned by the incapability of the technician. I am the technician who prepared the serum, and in justice to yourself and to me I believe you should be advised of the outcome of the investigation that followed the death.

A coroner's jury composed of reputable physicians from all parts of this county returned a verdict exonerating me from liability and attributing the contamination of the serum to undetermined causes. It is true that they recommended state supervision of all laboratories engaged in making serum, but they did not in any manner lay the blame for this most unfortunate happening to me or to my laboratory.

The doctors composing the jury are as follows: Dr S S Bogle, Dr Lighton Ray, Dr C M Carlson, all of Santa Rosa, Calif, Dr James G Anderson, Dr M L Lewis, Dr H S Rogers and Dr S Z Peoples of Petaluma, Calif, Dr Chester Marsh and Dr Ernest Vieira, both of Sebastopol, Calif, Dr E J Finnerty of Sonoma, Calif, Dr F O Butler of the Sonoma State Home, and Dr D C Oakleaf of Cloverdale, Calif.

ALEX A SOKOL, Santa Rosa, Calif

### ACUTE OUTBREAK OF TYPHOID

*To the Editor*—During a recent visit of a large circus in this city, fever was discovered in several of the performers and laborers attached to the organization. Steps were immediately taken by the local health authorities, the chief physician of the circus, and members of the staff of Harper Hospital to examine every member of the group. July 23 and 24, seventy-eight men and women, ranging from the age of 15 to 50, were found to have typhoid or were suspected of being in the early stages of the disease. All of them were brought into Harper Hospital and isolated in a separate division of the hospital. Complete isolation precautions with a separate staff of nurses and physicians were placed in charge. Blood cultures and Widal tests were immediately done on the entire group.

At this time, forty-seven of these patients have been definitely proved to have a typhoid bacillus bacteremia. Twenty have been discharged after careful and repeated blood cultures, Widal tests and negative stool cultures.

The origin of the infection has not been fully determined. The Detroit Board of Health and the Michigan State Board

of Health have been investigating this phase of the problem. Among those isolated at Harper Hospital, no typhoid carrier was found among the food handlers. The date of the onset of the disease in each individual has varied. Some date the onset of their symptoms as early as July 9, others as late as July 23. The disease appeared among the performers who never are permitted to eat food prepared in the mess kitchen that supplies food to the crew of the circus.

Seven women have the disease. The majority of one team of aerial performers is afflicted. Among the other members of the circus, the disease is spread among laborers, ticket seller, electrician and barber.

All but about twelve have typhoid in a severe form. One patient died in a state of hyperpyrexia.

This preliminary report is made for the purpose of recording this unusual outbreak and will be followed later on by a complete report of the subsequent events, the treatment, and the sequelae of the disease.

HUGO A. FREUND, M.D., Detroit

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### TREATMENT OF FRACTURE OF RIBS

*To the Editor*—A white man aged 37 was struck on the back May 10 by some boards (truck mats) which fell a distance of about 8 feet as they were being lifted by a crane. The boards are estimated to weigh half a ton. They struck the patient a rather glancing blow, causing extensive abrasions on his shoulders and back. Roentgen examination revealed fractures of the first rib on each side at about the junction of the anterior and middle thirds with separation of a good quarter inch in each fracture. My theory is that the great depression of the clavicle caused it to fracture the ribs though no other ribs were broken, nor was either clavicle. Now after a period of six weeks there is still distinct crepitus in the fracture on the right side and roentgenograms reveal no callous formation and no diminution in the amount of separation on either side. The treatment has consisted of rest and the avoidance of muscular exertion. If you have any suggestions as to the proper procedure to obtain union in these fractures I will appreciate it. I can find very little in the literature on this type of fracture. What will be the prospect for permanent disability? When will it be safe for the man a laborer to resume work?

ROBERT H. WRIGHT JR. Phoebus, Va.

*ANSWER*—A bilateral fracture of the first rib as a result of a blow on the back is uncommon. Such fractures may occur from a fall which causes the body to jack-knife sharply, so that the lower ribs are driven against the pelvis and the weight of the head and shoulders is driven downward and forward on the upper ribs. The fracture described in this note can be explained on this basis.

Rib fractures usually heal within a period of six weeks regardless of whether or not any immobilization is obtained. It is the practice of most clinics to strap the chest tightly passing the adhesive tape around over an axillary pad and extending from near the midline in the back on one side and around in front to near the midline in the back on the opposite side. A second strip of adhesive tape should be placed from just below the axilla and posterior to it, around in front and over the opposite shoulder to the back, and a third similarly placed beginning below and behind the opposite axilla and passing upward and over the shoulder of the opposing side. This type of adhesive strapping can be worn for as long as three weeks unless the patient's skin is unusually susceptible to irritation from zinc oxide.

These fractures will probably unite and there will be no permanent disability. The patient should not be allowed to return to work until there is clinical evidence of union characterized by absence of crepitus, palpable tenderness, respiratory pain and possibly the presence of palpable callus, which can usually be demonstrated in the roentgenograms. It is well known that large sections of ribs can be excised surgically with subsequent complete restoration through periosteal new bone formation. The fact that there has been separation of the ends of the fragments in this case no doubt accounts for the delay in union but the prospect for ultimate complete recovery should be good.

### CAUDAL BLOCK ANESTHESIA

*To the Editor*—I wish to ask your opinion regarding a problem in regional anesthesia. I have used sacral (caudal) anesthesia frequently in the past, and still prefer it for rectal and perineal work. However, in about 20 per cent of the cases for no reason that I can discern the anesthesia fails to work. My technique is identical for all the cases in which I use it and in the majority of cases it gives satisfactory anesthesia. I use 30 cc of 2 per cent procaine hydrochloride and introduce it at a depth of about 6 cm through the sacral hiatus. The patient rests on her back for one-half hour before the operation is started. The books to which I have referred do not explain the failures which occur in the experiences of numerous other men besides myself. Can you explain the failures in detail and advise steps to obviate them? Kindly omit name.

M.D., New York

*ANSWER*—Caudal block by means of 30 cc of 1 per cent procaine solution, injected into the caudal canal, has an incidence of unsatisfactory anesthesia of about 30 per cent. There is, of course, always at least partial anesthesia as a result of the injection. In some cases the perineum and anus will show areas of anesthesia, hyperesthesia and small areas of normal sensation after such an injection. With the use of the 2 per cent solution there is some reduction in the percentage of cases in which there is failure to obtain anesthesia. With the 3 per cent solution this percentage is still further reduced. However, the facts that a solution stronger than 1 per cent procaine is not advised by the American Medical Association Committee on Anesthetics and that, from clinical experience, reactions to intravenous injections of procaine solution occur occasionally in connection with sacral block, indicate that the most practical solution is 1 per cent procaine hydrochloride. From 25 cc (in small persons) to 35 cc (in large individuals) may be injected in the caudal canal, 10 or 15 cc of 1 per cent procaine solution should be injected in each second sacral foramina. Anesthesia should appear in about twenty minutes and is usually satisfactory. It is important, in placing a needle in a foramen, to be sure that the foramen has been entered. This may be ascertained by advancing the needle for one-half inch after one thinks the foramen has been entered. Then the needle may be withdrawn so that the point of it is just inside the opening of this bony foramen. The test to make sure that the caudal needle is in the caudal canal is to bring the needle against the posterior bony wall of the caudal canal. This test is applicable except when there is spina bifida occulta of the sacrum. Many of the failures to induce sacral block anesthesia with the caudal injection are due to failure to enter the caudal canal. Occasionally an individual is so certain that the caudal canal has been entered that he can be convinced that it has not been only when the needle is withdrawn and reinserted and anesthesia produced after the second attempt. Anesthesia is sometimes delayed when the solution is very cold. Vigorously boiling the procaine solution causes it to lose its effectiveness. If anesthesia is to be produced with still greater certainty, injection of the caudal canal through the second, third and fourth sacral foramina on each side should be carried out.

### FATE OF BARBITURIC ACID PREPARATIONS IN BODY

*To the Editor*—Can you give me references to literature or information concerning the fate of the different barbituric acid preparations after they enter the body? Is there any accurate clinical information to show that the different products on the market differ in any way in their action when taken in comparable amounts? Is there any chemical reason to suspect that they should in any way be different? Kindly omit name.

M.D.

*ANSWER*—Of the barbituric acid derivatives studied in this connection, barbital and phenobarbital are largely excreted as such in the urine (barbital about 85 per cent, phenobarbital about 30 per cent), amytal and pentobarbital appear in the urine only in traces or not at all. Nephrectomy markedly prolongs narcosis from barbital and from phenobarbital but not from amytal, pentobarbital, neonal, ipral, dial allurate, phanodorn or pernocton. Experimentally produced liver damage in animals (to an extent such that disappearance of bromsulphalein from the blood is significantly delayed) does not appreciably affect the duration of action of barbital but does prolong the action of pentobarbital. It appears from these studies that recovery from the influence of barbital or of phenobarbital is dependent largely on excretion of the compound by the kidneys, whereas recovery from narcosis by amytal, pentobarbital, neonal, ipral, dial, allurate, phanodorn

or pernocton is dependent on destruction of the drug in the body. In the case of pentobarbital an important, if not the only, site of destruction appears to be the liver, presumably this is true of the other members of this group also. The end products of these compounds have not been isolated. There is considerable clinical evidence of differences in the effects of the various barbituric acid derivatives. It is obvious from the foregoing that barbital or phenobarbital should not be employed in cases in which significant kidney damage is present and that pentobarbital (and presumably the others of the group) should be employed with care if at all in patients with impaired liver function. The other differences are concerned chiefly with duration of action, pentobarbital being the shortest acting member of the series of those given orally (evipal appears to produce even a shorter effect but this drug is given intravenously) and barbital probably the longest. Some of the drugs, like evipal and pernocton, have a tendency to produce clonic muscular spasms in occasional individuals. The barbiturates also differ in the ratios of their effective and fatal doses, this, however, is of little consequence in ordinary clinical usage, as the safety factor usually is sufficiently great even with the more toxic preparations. #### SCHULZ-CHARLTON REACTION IN SCARLET FEVER

To the Editor—A child aged 10 complained of lassitude, slight soreness in the epigastrium and fever of six hours' duration. Examination disclosed marked flushing of the face, a diffuse red eruption limited to the abdomen, the neck, the thighs, the arms and the chest, slight dusky redness of the anterior pillars in the throat, the tongue clear of a deep red, the papillae standing out prominently and almost transparent. The anterior cervical glands were slightly enlarged. The temperature was 102.2 F and the pulse 120. The throat was not sore, there had been no vomiting, the onset was so gradual as to escape the attention of the unusually vigilant mother and the Schulz-Charlton test produced no change in the color of the rash. The child had German measles two months ago and the rash cannot be attributed to recent drug administration. Another physician maintains that even with a negative Schulz-Charlton test the picture of rash fever and strawberry-like tongue must be diagnosed as scarlatina, while my understanding of the Schulz-Charlton test warrants a negative diagnosis in the case. Possibly I place too much emphasis on the infallibility of the Schulz-Charlton reaction, but if my understanding of the reaction is correct, i.e., that it is in effect a neutralization of the toxin in the skin by the specific antiserum, I should conclude that the test is infallible. Kindly omit name and address.

M D Wisconsin

ANSWER—The Schulz-Charlton test is not always infallible, because the rash is sometimes too slight to show a good area of blanching, because the rash is old with extravasation of blood into the skin, or because there may be a central area of reddening due to the reaction of the skin to the serum itself. In case horse serum is used or to the preservative in case preserved convalescent serum is injected, in this case, however, there can usually be seen an outer zone of blanching surrounding the central red area. With the exceptions noted, the Schulz-Charlton reaction is positive in scarlet fever.

Nose and throat cultures made on blood agar plates and examined for the presence of hemolytic streptococci would be helpful in diagnosis.

#### DIGITALIS IN TREATMENT OF FAILING HEART

To the Editor—Would you kindly through the medium of your journal evaluate the use of digitalis in old hearts with moderate decompensation but no fibrillation. My experience with the latter drug at the local hospital here in a large number of cases is that the added strain in spite of the better nutrition of the heart hastens rather than prolongs the final outcome. What is the present status of theobromine in these cases? Kindly omit name and address.

M D New York

ANSWER—There is no evidence indicating that the administration of digitalis places an added strain on the failing heart. On the contrary, when the myocardium is laboring under difficulty, digitalis exerts a tonic effect on the heart muscle and augments cardiac output. It is essential to use a potent biologically standardized preparation, in proper dosage. In many

elderly patients, after compensation has been restored, continuous administration of digitalis in maintenance doses (from 0.1 to 0.2 Gm, or 1½ to 3 grains, each day) will often serve to prevent the recurrence of congestive heart failure.

Theobromine, like the other members of the xanthine group, has a double action. (1) It dilates the coronary arteries and thereby increases the volume of blood that flows through the heart muscle, (2) it is a mild diuretic. It is therefore sometimes useful in cases of coronary sclerosis, or in the presence of edema. It is usually given as theobromine sodiosalicylate in doses of from 0.65 to 1 Gm (10 to 15 grains) three or four times a day. The xanthine preparation at present most commonly employed for the relief of anginal pain is theophylline ethylenediamine. It is dispensed in tablets of 0.1 Gm (1½ grains) each, one of which may be given three or four times a day over a period of weeks or months.

#### MUSCLE SPASM AND CRAMP

To the Editor—A woman aged 42 is subject to painful contractions of the muscles. The condition began twelve years ago in the muscles in the calf of the right leg. It now involves the muscles of all limbs and at times the muscles of the trunk. These contractions come on particularly on exertion. In the arm for instance lifting a heavy pan of water will cause a contraction of the biceps which may last three days. The muscle will remain hard and tender, extension of the forearm at the elbow is possible but painful. There should be no foci of infection present. She has had 20 grains (1.3 Gm) of calcium lactate three times daily but can see no change. I should like to know whether you can offer any suggestions. Please omit name.

M D, North Dakota

ANSWER—From the description of the muscle spasms, lasting as long as three days, the spasm must be tonic. Muscular cramps of this type usually fall into the group of tetany on the basis of calcium deficiency. A condition of this type lasting for twelve years without more evidence of the cause is most unusual. Parathyroid disease should be considered. The diagnosis of tetany may be made by observation of its other phenomena, Trousseau's sign, Erb's symptom and the Chvostek sign together with the finding of a low level of blood calcium. The administration of calcium in the dose mentioned might be totally inadequate without the use of parathyroid extract or possibly viosterol. Larger doses of calcium alone, from 8 to 12 Gm daily, are capable of raising the calcium level of the blood and relieving the symptoms of tetany.

In the event that the calcium metabolism is found to be normal, other causes for increased muscle irritability of a chronic type must be considered. These are most likely to be of central origin. Lesions involving the pyramidal tract might be considered, but the neurologic examination should be conclusive. The neurologic conditions producing increased muscle irritability usually result in contractures, with muscle weakness and muscle atrophy, rather than cramps.

#### HEALTH HAZARDS IN CLEANING INDUSTRY

To the Editor—I should like information on the probability of poisoning in the following case. A woman aged 55 who is employed by a large department store, became ill after cleaning a considerable number of garments for several weeks with chloroform and oronite (a cleaning solvent sold by the Standard Oil Company). A man working with her also became ill. The symptoms in both cases were referable to the stomach. My patient complained of a bad taste in the mouth, a coated tongue, a burning sensation in the throat and sensations of burning and fullness under the sternum. Examination revealed nothing of significance except the coated tongue and gastric juice of low acidity containing large amounts of mucus. It has been reported to me that the man believes he has a cancer of the stomach. Is it possible for chloroform poisoning to result from a contact of this type? The workroom at the time was poorly ventilated but now an exhaust fan has been installed. Are you familiar with cases of oronite poisoning? Gloves were not worn.

J H GIVENS M D Seattle

ANSWER—This query fails to provide adequate information as to the extent of exposure. Naturally the exposure would be greater if actual submerging of garments took place in contrast to spotting work. An inquiry was made of the Standard Oil Company of the area in which this reply originated. The company stated that it had no knowledge of any such product as oronite but indicated that other companies of the same name might make or market such a product. In any event, such a product might be expected to contain as its major ingredient a petroleum fraction of the general range of naphtha. The somewhat noncharacteristic symptoms described might arise from causes other than industry but if they are attributable to industrial sources either the chloroform or naphtha readily might produce just the clinical picture suggested. Chemically, chloroform is similar to carbon tetrachloride, which is commonly accepted as highly toxic. In addition, chloroform is said to possess a toxicity 22 times as great as carbon tetrachloride.

Even in a mild case, such as this may appear to be, a headache and a diarrhea usually accompany the manifestations indicated as present. In severe cases of chloroform toxicity the chief symptomatology can be traced to the liver, which may undergo necrosis. Guanidine poisoning may arise. The damage done by chloroform may be followed by rapid and complete recovery if further exposure is avoided, but the damage from naphtha may be prolonged or permanent. Condemnation is to be extended regularly to the extensive use of chloroform for dry cleaning except under conditions completely protecting the worker against exposure—especially against the inhalation of vapors.

#### SYPHILIS OF NERVOUS SYSTEM

*To the Editor*—I should like your advice as to the therapy in the following case. A man aged 34 had syphilis about eight years ago and at that time had a year's treatment by vein. About four weeks ago he became morose, languid and irresponsible. He lies and looks at the ceiling for hours at a time and takes no interest in anything going on around him. His Wassermann reaction is 4 plus. No spinal fluid test has been done but it would undoubtedly be positive. All reflexes are increased. Could you kindly advise as to therapy with respect to drug, dosage and frequency? Please omit name. M D California

**ANSWER**—Further studies are essential, including examination of the spinal fluid, in order to determine the location of the syphilitic infection, without them a rational selection of therapy is not possible. It may be that there has been a parenchymatous invasion of the central nervous system—a dementia paralytica. Therapy in this condition would differ largely from that in other forms of syphilis and would include the selection of some form of fever-producing means, the administration of trypanamide, or both. This selection must be based on a thorough study of the eyes, the cardiorenal system, and so on.

#### FOOD OF THE CHINESE

*To the Editor*—THE JOURNAL January 27 published an editorial comment called "A Dietary Ingenuity." I should like to ask the author where the recent analyses of Chinese foods and the discussion of culinary methods in providing adequate calcium by Frances Clinton may be found. LAVERGNE DEANISON Nutritionist Pittsburgh

**ANSWER**—The author of the item referred to in the *Journal of Home Economics* (25 871 [Dec.] 1933) writes: "Despite the fact that the Cantonese do not use any milk or milk products, the diet of these Chinese people is adequate in calcium, protein and calories, according to Pih Wan Hoh, a graduate student in home economics at Oregon State College, whose home is Canton, China. At a recent quarterly meeting of the Oregon State Nutrition Council Miss Hoh discussed in detail the eating habits and customs of Chinese among the better classes of city people as she has known them in southern China." Details regarding these statements can doubtless be secured by correspondence with the Department of Home Economics at the Oregon State College in Corvallis. For expert information regarding the composition of the foods of the Chinese, it may be advisable to consult Prof. William H. Adolph, Department of Chemistry, Yenching University, Peiping, China. He has made extensive investigations and published numerous papers, partly in Chinese journals, on this subject.

#### TREATMENT OF RED NOSE DUE TO PERMANENTLY DILATED CAPILLARIES

*To the Editor*—I have a patient with a very red nose. Only the skin is involved. It is smooth. The capillaries are dilated and it bleeds profusely when cut. It becomes violet or cyanotic on exposure to cold. The condition was thought to be a chronic erysipelas and protein shock therapy was used with no results. There are no pustules and a smear revealed sebaceous material but no organisms. The patient has never had any constitutional symptoms. He works hard in a lumber yard and paint shop. The blood pressure is normal. There is no erythema of the ears or extremities. Is this an infectious process or a vascular disturbance? What is the treatment? What substances are best for the intradermal injection of hemangio-ectasia (port wine stain) besides hot water? Could they be used in this case? Please omit name and city. M D Arizona

**ANSWER**—These cases are not infectious but are due to paralysis of the vasoconstrictor apparatus controlling the capillaries and venules of the skin. This apparatus is more sensitive in the center of the face than anywhere else, responding readily to various stimuli. After many and frequent responses of this kind, the constrictor apparatus wears out and the dilatation becomes permanent. In a typical case of acne rosacea this involves the nose, adjacent cheeks, the center of the forehead and the center of the chin, but in certain cases, as in

the one under discussion, it is confined to a smaller area, for reasons unknown.

Exposure to extremes of temperature, either cold or heat, are responsible, at least in part, for some cases. Obstruction to the circulation within the nose or a pustular folliculitis in the nares can be blamed for some cases. Focal infection about the teeth, in the tonsils or in the nasal cavity or its neighboring sinuses should be sought and eliminated if found. The gastro-intestinal tract should be thoroughly investigated. Hypoacidity, liver or gallbladder disease, or constipation may be at fault. The diet should contain no irritating foods or drinks. Very hot foods or drinks, alcohol in any form, tobacco, tea, coffee or chocolate, condiments, and rich meat dishes or desserts should be prohibited. In view of the patient's occupation, the possibility of chronic lead poisoning should be investigated.

Even though some such condition may be discovered and corrected, local treatment may be necessary before success can be achieved and in too many cases local treatment is the only hope. Constricting lotions, such as lotio alba, composed of sulphurated potassa, 2 Gm, and zinc sulphate, 2 Gm, in rose water to make 30 cc, may be used. The lotion should be dabbed on before retiring and allowed to dry on. Care should be taken in washing not to use very hot or very cold water. Lotio alba can be strengthened by increasing the solid ingredients or by the addition, after the lotion is made, of resorcin up to 10 per cent.

Röntgen rays, low voltage unfiltered, in doses of from 37 to 75 roentgens, from one eighth to one-fourth erythema dose, once a week until a total of two whole erythema doses or 600 roentgens has been given, is often successful. If the skin becomes dry and wrinkled during the treatment, no more roentgen rays should be given until this condition has cleared. There is more danger of overdosage in acne rosacea than in acne vulgaris because the patients are older, as a rule. Local medication, except soothing applications, are taboo during roentgen treatment.

If these measures fail, carbon dioxide snow, easily obtainable as dry ice, may be tried, a stick not over 1 cm in diameter being used, applied with fair pressure for one second on each spot. If this causes no reaction and no improvement, the time may be cautiously increased until a slight reaction is obtained. By using a small stick and making many slight applications, one may avoid the checked effect due to strong applications that cannot be made to cover the whole area exactly alike.

If it is thought necessary to use injections such as are used in the treatment of angioma, sodium morrhuate, 3 per cent solution in oil, is one of the best. It should be injected if possible into the venules (Biegeleisen, H. I. Telangiectasia Associated with Varicose Veins, THE JOURNAL, June 23, p. 2092) at points 2 cm apart near the border of each patch. A week later injections should be made between these points. As the border clears up, injections should be made nearer the center.

Electrolysis for the larger venules, the needle being inserted on the negative pole into the venule and a 1 to 2 milliampere current being allowed to circulate until the area has turned white, is also a helpful procedure.

#### URINE OF LOW SPECIFIC GRAVITY

*To the Editor*—Please inform me as to what will cause low specific gravity in a urine specimen for example 1.001 or 1.002? I have had several of these cases of late and can find no reason for it in the text books. In none of the cases has there been any cardiac involvement and in no case has there been any rise in blood pressure. My latest case is one of a woman seven months pregnant who feels perfectly well but who has gained 11 pounds (5 kg.) in the past month. Also what could cause the great gain in weight? M D, Michigan

**ANSWER**—A urine of a specific gravity as low as 1.001 or 1.002 in a twenty-four hour specimen occurs only in diabetes insipidus. This is an uncommon condition due to a lesion of the posterior lobe of the pituitary gland or the adjacent area of the brain. In this disease the urine volume may reach from 4 to 30 liters daily. The patient naturally has great thirst and drinks equally large quantities of water. Solution of pituitary usually causes a return to normal volume.

The specific gravity of the urine varies greatly during the day, depending chiefly on the fluid intake, perspiration and nervous functional disorders. The total solids excreted daily are but slightly variable when compared with the fluid variations. Hence the specific gravity tends to vary in inverse ratio to the alterations in volume.

The normal range of specific gravity is from 1.008 to 1.028, with most results between 1.015 and 1.025. Except after the ingestion of great quantities of water a specific gravity as low as 1.001 or 1.002 is found only in diabetes insipidus. The

polyuria of chronic nephritis or hypertensive cardiovascular renal disease is associated with a lowered or fixed specific gravity, but the values are usually between 1008 and 1013.

From the foregoing statements it is obvious that the specific gravity of the urine, to be of value, must be taken several times during the day, or the total twenty-four hour specimen tested. Variations from 1002 or 1003 to 1030 may occur in normal persons without indicating any pathologic condition.

#### TREATMENT OF MYELOGENOUS LEUKEMIA

*To the Editor*—I am treating a case of myelogenous leukemia with the usual discouraging result and am writing you on the chance that you may have knowledge of some relatively new and successful procedure in the handling of this disease. I desire especially to learn of anything that is more successful than iron, arsenic and liver extract by mouth, transfusion and roentgen therapy.

OTTIS LIKE, M.D., Monroe City, Ind.

*ANSWER*—No new or more successful remedies of value in the management of myelogenous leukemia than those enumerated have appeared in recent years. Irradiation (with either x-rays or radium), while efficient in effecting clinical improvement and reducing the white blood count in the early stages of the disease, cannot be considered a cure, nor does it seem to prolong life. The disease continues to run an average course of about three and one-half years. Ultimately all patients with myelogenous leukemia lose their radiosensitivity and the employment of radiation under such circumstances or in the acute stage may be disastrous. A judicious use of radiation, therefore, seems to offer the greatest benefit that is possible to give. Iron, arsenic, liver feeding and transfusions may be employed as adjuvants.

#### BLOODY PLEURITIC FLUID AND CANCER

*To the Editor*—It has frequently been said that bloody pleuritic fluid is pathognomonic of cancer of the lung. Is this altogether true? Are there not other conditions that will produce a bloody pleuritic effusion? Kindly send me the list of other conditions that may produce such effusion. Please omit my name.

M.D. Indiana

*ANSWER*—A bloody pleuritic fluid is not pathognomonic of cancer of the lung. It may be caused by a malignant disease of the pleura and by inflammatory and traumatic conditions of both the lung and the pleura. Occasionally a tuberculous effusion will be blood stained. There is a type of spontaneous pneumothorax associated with large amounts of bloody effusion that may or may not be of tuberculous origin.

#### EFFECTS OF CALCIUM ON COAGULATION TIME

*To the Editor*—I am told that calcium gluconate given in a dosage of from 100 to 150 grains (6.5 to 10 Gm.) a day will decrease coagulation time at the end of twenty-four hours but that if the same dosage is continued for three or four days there will be an increase of the coagulation time. Please advise me about this.

GEORGE E. VAUGHAN, M.D., Louisville, Ky.

*ANSWER*—The injection of calcium gluconate for three or four days in the doses mentioned will not increase the coagulation time in man. There are some *in vitro* studies on citrated blood which indicate that oversaturation with calcium may interfere with the clotting mechanism, but this cannot be substantiated *in vivo*.

#### INJECTION TREATMENT OF VARICOSITIES OF VULVA

*To the Editor*—Is there any contraindication to the treatment by sodium morrhuate of varicosities of the vulvar region during the sixth month of pregnancy? Please omit name.

M.D. New York

*ANSWER*—The injection treatment of varicose veins of the saphenous system during the first seven months of pregnancy is a safe and good practice in experienced hands. Quinine, of course, is not used. There is no complete agreement, however, in treating vulvar varicosities, which drain only to a slight degree toward the saphenous system and are mainly tributaries of the internal iliac vein. An injection of sodium morrhuate into the vulvar veins may, although it undoubtedly hardly ever does, set up a pelvic thrombophlebitis. It is pertinent to ask how often such vulvar varicosities rupture and bleed during delivery and whether injections would prevent vulvar hematomas. It is also obvious from a glance at the hugely dilated venous network of the vagina and vulva of the pregnant woman, that a few injections into the periphery of such a venous plexus can hardly obliterate more than a few short segments. There is at no place an isthmus or common trunk comparable to the terminal portion of the saphenous vein. From such considera-

tions it would seem that the injection of vulvar varicosities, while practiced by some eminent workers in this field, has not much to offer and may lead to complications.

#### ASTHMATIC ATTACK DURING COITUS

*To the Editor*—A case was recently brought to my attention of a woman suffering from asthma who states that the act of coitus with the husband brings on an attack of asthma. Could this be so? Could you refer me to literature regarding similar cases? Please omit name.

M.D., British Columbia

*ANSWER*—This condition is relatively common and is caused by sensitiveness to the effect of heat and effort (Duke, W. W. *Arch. Int. Med.* 45:206 [Feb.] 1930). It is frequently attributed erroneously to sensitiveness to spermatozoa. The same condition is a relatively common cause of impotence in man. It can be benefited in either case by a cold bath and avoidance of heat and effort prior to coitus. Furthermore, the weakness can be benefited by the effect of graduated exercise of the voluntary muscles.

#### EMBRYOLOGY OF EAR

*To the Editor*—Will you kindly inform me at what age the ear has attained its full growth?

M.D., Pennsylvania

*ANSWER*—The labyrinth of the ear undergoes slight, if any, changes after birth, that is, it has attained adult form at birth. As regards the middle ear, the situation is different. The drum membrane at birth has attained its adult form, as have the ossicles lodged in the middle ear. The external auditory meatus, at birth, consists only of the cartilaginous membranous part, which is attached to the os tympanum. There is no mastoid process or pneumatic cells. During the first decade the external meatus begins to take on its adult characteristics whereby the inner two thirds is made up of bone derived in part from the os tympanum, in part from the squamous bone, and a wedge-shaped segment of the upper posterior part of the meatus derived from the petrous bone. The development and pneumatization of the mastoid process begin during the first year and are practically complete by the tenth or twelfth year.

#### BILIVACCIN STILL EXPERIMENTAL IN TYPHOID

*To the Editor*—Please advise me as to the relative efficiency of immunization against typhoid by the hypodermic injection of killed bacilli and by the use of the Bilivaccin tablets by mouth. Is the Bilivaccin immunization against cholera and dysentery effective? And if so to what degree? Please omit name.

M.D. India

*ANSWER*—The only safe and generally accepted method of immunization against typhoid is by the injection of vaccines composed of killed bacilli. The use of "Bilivaccin" is still strictly in an experimental stage in the three diseases mentioned. Neither this product nor any other "vaccine" product recommended for oral administration has been accepted by the Council on Pharmacy and Chemistry.

#### TOBACCO COUGH IN CIGARET SMOKERS

*To the Editor*—Please give me your opinion regarding the cause of so-called tobacco cough seen commonly in cigaret smokers. Is it possibly caused by the fine particles of loose tobacco or tobacco dust?

G. LANDE GATELY, M.D., East Boston, Mass.

*ANSWER*—It is difficult to say definitely just what causes the so-called tobacco cough, but it is likely that several factors may be present. Not only do fine particles of tobacco enter the throat, but the heat of the fumes, the nicotine vapor, plus the products of partial combustion may be direct sources of the irritation. This is probably especially true with the inhalation of the smoke into the lungs such as is indulged in by the vast majority of cigaret smokers.

#### SINGLE TESTICLE AND POTENCY

*To the Editor*—A patient aged 29 married in five physical condition is sexually potent but possesses only one testicle. He states that the other disappeared up the inguinal canal at puberty. The patient is anxious to know what his possibilities are in regard to sterility. Please omit name.

M.D. Illinois

*ANSWER*—The fact that a man possesses only one testicle does not render him sterile as long as the one testicle is healthy and the various genital tubes are patent. The question can be definitely determined by the examination of a condom specimen, which should contain numerous motile spermatozoa.

## Book Notices

*Modern Clinical Syphilology Diagnosis Treatment Case Studies* By  
John H Stokes MD Duhling Professor of Dermatology and Syphilology  
in the School of Medicine University of Pennsylvania Second edition  
Cloth Price \$12 Pp 1400 with 973 illustrations Philadelphia &  
London W B Saunders Company 1934

This monograph, first published in 1926 and reprinted in 1927  
and 1928, the author has now found necessary to revise and  
rewrite. Many changes have been made. As the author him-  
self states, fifteen of the twenty-three chapters have been com-  
pletely rewritten and a new chapter on relapse and progression  
has been added. The book has been written for the completely  
uninitiated practitioner and student, as well as for the expert  
syphilologist. That the author has achieved this dual purpose  
and yet kept it entirely readable, there is no doubt. The dis-  
cussions on progression, relapse and cure in syphilis are  
thorough and brought down to the latest continental and  
American views on these subjects. The chapter on the funda-  
mental principles of treatment has been intelligently handled.  
The latest views in regard to types of arsenical and bismuth  
salts used in the treatment of syphilis are carefully considered.  
The use of acetarsone in the treatment of syphilis is discussed,  
and Dr Stokes feels that this drug is not yet sufficiently per-  
fected and studied to be safely used by the general medical  
man. He also advises only such antisyphilitic medicaments as  
are approved by the Council on Pharmacy and Chemistry.  
Throughout the volume the enormous statistical material from  
the Cooperative Clinical Group of five American University  
Syphilis Clinics, working in cooperation with the United States  
Public Health Service, has been utilized to bring out various  
factors as to the epidemiology, pathology, diagnosis and treat-  
ment of various phases of syphilis.

In such a well written volume it is difficult to pick out  
chapters for special mention. The chapters on the problems of  
immunity and syphilis, on cardiovascular syphilis, on central  
nervous system syphilis and on syphilis and pregnancy have  
been particularly well written.

Much value has been given to the book, for the student and  
the practitioner, through the case records, through the excellent  
illustrations and through the discussions of differential diagnosis.

On the other hand, the expert will find plenty of food for thought and sufficient citations at the beginning of the chapters to guide him into any channels that he may desire to follow through.

Naturally, in a formidable volume of this type it is impossible to devote as much space to each problem as could be desired. Possibly syphilis of the rectum and its relation to inguinal lymphogranulomatosis should have been more fully discussed. Moreover, despite their importance in differential diagnosis from syphilis, no mention of esthiomene or of the anorectal syndromes of lymphogranuloma inguinale is even made. In the tabulation of bismuth preparations on pages 252 and 253, figure 115, it is unfortunate that the amounts of metallic bismuth per dose have not been more carefully worked out. For example, the metallic bismuth content of bismuth oxychloride is 80 mg per cubic centimeter. It is difficult to figure out how a 2 cc dose would thus contain 0.2 mg of metallic bismuth. The milligrams of metallic bismuth in Biliposol is incorrectly put as 0.180 with a 2 cc dose. It should have been 0.080. There are numerous other errors in this one figure 115 that should be corrected in the next revision.

Throughout the entire volume there is a tendency to use the term "gland" for "lymph node," as on pages 657, 688, 966 and 1045, though in most places the proper term "lymph node" is employed. This is, no doubt, simply an oversight. And yet, for such a large volume it is remarkable how few mistakes have been made.

As far as is known, there is no single volume in the French, German or English language that so fully and so authoritatively handles syphilis as does this volume of Professor Stokes. One marvels that any one physician could be at the same time competent enough and brave enough to handle such an enormous task. The book is a landmark in American and continental medicine and is bound to be quoted more and more frequently as physicians become familiar with its scope, probity and clarity. It can be unhesitatingly recommended to both the practitioner and the expert syphilologist. It should be an integral part of every physician's library, for where is the physician or the specialist who at some time or other does not come into intimate contact with syphilis in his particular patient?

As far as the format and binding of the volume are concerned, it is especially well done. Moreover, a painstaking index of subjects and of authors, amounting to seventy-four pages, is appended.

*Chirurgie Infantile d'urgence* Par M. Fèvre. Préface du P<sup>r</sup> Ombredanne. Paper. Price 70 francs. Pp 452 with 110 illustrations. Paris: Masson & Cie 1933.

This is a new monograph by Fèvre covering urgent surgery of infants and young children. The author, an assistant of Professor Ombredanne, offers this volume as a complement to the third edition of Ombredanne's *Precis clinique et opératoire de chirurgie*, which appeared in 1932. The volume is prefaced by a complimentary criticism by Ombredanne, who admits that Fèvre is justified in adding the volume to supplement his own relative to urgent surgical conditions, as there is need for additional details concerning preoperative precautionary management and postoperative care both of which are of such great importance, particularly in the emergency surgery of infants. Besides this it is well to have some of the newer urgent operations described in greater detail with proper emphasis given to their indications. This volume, therefore, truly supplements the one by Ombredanne, and the two together represent a valuable contribution on the work done by this large children's surgical service. This new volume presents, in valuable detail, the clinical considerations concerning the indications, preoperative preparation, operative procedures and postoperative management of the surgical emergencies of infants and young children as these are carried out in this important clinic today. The operative procedures consist essentially of those which are used and found most valuable. It is a volume based on personal experience. The material begins with a short chapter on general preoperative and postoperative considerations, including the choice of anesthetic, complications during and following operation, blood transfusion, and hemophilia. The largest part of the volume considers the urgent surgical conditions of the various regions of the body. This

is followed by a chapter on general infections and burns. The final chapter discusses congenital malformations demanding immediate surgical intervention. The indications of operation are thoroughly discussed. When they vary, depending on the age, the pathologic variations and the clinical course at various ages, he discusses them in the case of the newly born, young infants, young children and, in some instances, older children. The considerations are handled in a masterful manner and the information is down to date. The operative details are similarly handled and the book contains a vast amount of valuable, practical, clinical information. It is not at all a mere catalogue of well known fundamental facts but, instead, a scholarly presentation and critical analysis of present knowledge.

This volume, together with Ombredanne's volume, constitutes a valuable presentation of modern surgery in infants and young children.

*Arbeit und Gesundheit. Sozialmedizinische Schriftenreihe aus dem Gebiete des Reichsarbeitsministeriums.* Herausgegeben von Professor Dr. Martineel. Ministerialdrilling im Reichsarbeitsministerium. Heft 24. Die Folgen der Entmannung Erwachsener an der Hand der Kriegserfahrungen dargestellt von Professor Dr. Johannes Lange, Direktor der Psychiatrischen und Nerven-Klinik der Universität Breslau. Paper. Price 5 marks. Pp 178 with 2 illustrations. Leipzig: Georg Thieme 1934.

A series of cases of emasculation resulting during the World War are discussed by the author. He states that while the loss of the testes, after full sexual maturity, is not followed by serious consequences in a certain number of cases, marked somatic and psychic manifestations follow castration in a greater number. The problem is of social and forensic importance. The conclusion that emasculation results in epilepsy and in insanity is not true. Castrated individuals may be useful members of society. The author disagrees with the conclusions of Möbius that loss of the gonads results in diminution of combativeness and initiative, and to the dicta of Fischer that emasculation produces schizophrenia or schizophrenic tendencies. The loss of the testicles may create, the author states, serious somatic and psychic manifestations, such as eunuchoid retrogressive changes accompanied in some cases by gynecomasty and regressions of the secondary sex characteristics. The thyroid plays here no active part. The basal metabolic rating is reduced and psychic manifestations are frequent. While libido may persist for a long time, it is gradually blunted and finally disappears. Occasionally, sexual hyperexcitability is observed. Neurasthenic and vasomotor disturbances ensue. Castrates often become dull and apathetic, lose initiative and develop phobias and depressions resembling serious organic disease. Individuals of neuropathic type are particularly affected. Practically all the manifestations of the female climacterium become manifest. These gradually abate but often persist stubbornly, rendering the victim incapable of concentration or work (important in evaluating compensation). Castration results in discordant glandular endocrine interactions. Testicular transplantation seems in some cases to be followed by good results. If this is not practicable, large doses of testicular extract should be tried. The advisability of the castration of individuals with criminal tendencies is discussed. This is not only unjust but tends to aggravate, in the author's opinion, the existing condition by engrafting a new symptom complex. As a whole, the work is an excellent compilation of instructive material.

*Mental Hygiene in the Community.* By Clara Bassett, Consultant in Psychiatric Social Work, Division on Community Clinics, the National Committee for Mental Hygiene, Inc. Cloth. Price \$3.50. Pp 394. New York: Macmillan Company 1934.

The author, a well trained worker in the field of mental hygiene, has accurately gaged the need for authoritative information concerning the hygiene of the mind and has made a laudable effort to fill the void. She has produced an excellent book. No doubt repeated disappointments resulting from the lack of mental hygiene consciousness in physicians, nurses, lawyers, parents, teachers, educators and others led the author into the error of making her book too inclusive. In twelve chapters there is discussed the relation of mental hygiene to medicine, nursing, social service, delinquency and law, parental education, the preschool child, education and teacher training, the church and theological training, industry, recreation and psychiatric institutions and agencies. The chapters on medicine,

nursing and education are especially good. They point a need that continues to hamper progress in these fields and indicate clearly that mental hygiene should not be an adornment but a closely integrated part of medicine, nursing and teaching. The remaining chapters are not as distinguished as these three, but they do deserve reading by those who are seeking to raise the community to higher levels. Even though the book is not a comprehensive picture of the relation of mental hygiene to all the phases of community life, it is a decidedly stimulating exposition of several of these phases and it is a valuable contribution to a subject that is still sadly neglected by the community. The index and bibliography are excellent, but the questionnaires at the end of each chapter are of doubtful value, since they give a pedagogic aspect to a book that is fortunately not a textbook.

*Die Praxis der Nierenkrankheiten* Von Professor Dr. L. Lichwitz, Vorsteher der Inneren Abteilung des Montefiore Hospitals New York. Fachbücher für Ärzte. Band VIII. Herausgegeben von der Schriftleitung der Kiloischen Wochenschrift. Third edition. Cloth. Price 26 marks. Pp. 349 with 52 illustrations. Berlin: Julius Springer, 1934.

This is a scholarly exposition on diseases of the kidney. While the outline of the book has been changed little from its previous editions, the material has undergone a thorough revision and includes practically all the recent advances in the subject. Because of the exhaustive nature of its contents it will not be possible to give a detailed review in this column. The organization of the monograph allows the presentation of a vast amount of data to the reader in a concise form. The opening chapters concern themselves with definition and classification and the following chapters are on the anatomy and physiology of the kidney. It would seem that the reader might obtain a more comprehensive conception of the terms if he had first read the excellent chapters on anatomy and physiology. Few books on the kidney have presented the subject in such a fundamental way as this one does. The discussion of the physiologic and pathologic basis for separating the various disturbances of the kidney is particularly well done. The chapter on kidney function tests is as comprehensive an exposition of this subject as there is in print, yet the balance of the book is maintained and each subject receives its proper emphasis. The volume is deserving of a place on every reference library shelf. It is highly recommended for those who are desirous of having an intelligent understanding of the kidney and its derangements.

*Hypochlorémie et accidents post opératoires. Etude clinique pathologique et thérapeutique.* Par H. Chabanier et C. Lobo Onell. Paper. Price 2<sup>fr</sup> francs. Pp. 146 with 9 illustrations. Paris: Masson & Cie, 1934.

The authors go into considerable detail regarding postoperative complications which they classify in four main groups: (1) those resulting from hemorrhage, (2) those caused by infectious complications either at the local operative site or in some distant part of the body, (3) those caused by mechanical disturbances such as a mechanical intestinal obstruction and gastric dilatation and (4) those due to various toxic manifestations. The last group is considered in most detail and comprises a discussion, for the most part, of disturbed blood chemistry, resulting in uremia, alkalosis, acidosis, hypochloremia and other chemical disturbances. The cause, prevention and treatment of these conditions are discussed and the underlying chemical factors considered. Emphasis placed on the preoperative and postoperative treatment of patients makes this book well worth reading.

*Die normale und pathologische Physiologie der Milz.* Von Dozent Dr. Ernst Lauda, Assistent der II. medizinischen Universitätsklinik in Wien. Paper. Price 18 marks. Pp. 280 with 2 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1933.

For those who are interested in any phase of knowledge pertaining to the spleen, this work should be of great value. Its review of the literature is particularly international and well correlated and is systematized under headings especially adapted for ready reference without one's necessarily having to read the whole volume. The book is well indexed and therefore should be also of value for ready reference especially for those wishing immediate orientation for further detail study. It deals with both experimental and clinical facts and presents no par-

ticular theory as a dominant theme. The author has apparently submerged his own conceptions for the sake of breadth of scope, despite the fact that he has been a voluminous contributor to the subject. Such an extensive review of literature would naturally not lend itself to illustration.

*Handbook of Therapeutics.* By David Campbell. M.C. M.A. B.Sc. Regius Professor of Materia Medica and Therapeutics, University of Aberdeen. Second edition. Cloth. Price \$4.75. Pp. 444, with 72 illustrations. Baltimore: William Wood & Company, 1934.

The second edition of this rather small, practical book, which "aims to supply the medical student with sufficient knowledge to treat disease rationally," has been somewhat enlarged to permit of revision of many articles in the light of more precise current knowledge. Among the new features included may be mentioned the articles on celiac disease and on sprue, the discussion of the use of phenylethylhydantoin in chorea, the ketogenic diet in urinary sepsis and in epilepsy, the high carbohydrate diet in diabetes, cortical extract in Addison's disease, and carbon dioxide in asphyxia and in whooping cough. Praiseworthy is the author's attempt to "present the truth stripped of unnecessary detail, and to give the student a clear conception of principles without obscuring his mind by a mass of detailed information that, after all, can be usefully acquired only at the bedside." This does not mean that he has eliminated all detail. The real problem in a book dealing with special therapeutics, i. e., the therapeutics of the various diseases, is what details to omit. As, unfortunately, this handbook of therapeutics deals with diseases in much the same way as do the books on the practice of medicine and most other books now on the market, it will probably not lead to the establishment of special courses on therapeutics, as might happen were a book to appear that would deal with therapeutics from the standpoint of pathologic physiology.

**Hospital's Contract to Furnish Medical Services Enforceable**—The Colgin Hospital and Clinic, a corporation, alleging that, at the request of the defendant insurance company and on its promise to pay, it had treated one J. T. King, sued to recover charges for hospitalization and physicians' fees for professional services. The insurance company contended that, as a corporation could not legally practice medicine, the plaintiff, a corporation, could not collect its charges for professional medical or surgical attention it rendered a patient. Judgment was given in favor of the Hospital and Clinic, and the insurance company appealed to the court of civil appeals of Texas, which certified certain questions to the Supreme Court of Texas. The Supreme Court seems to have referred the questions to the commission of appeals of Texas, section A.

In ordinary acceptance, said the commission of appeals, a sanatorium is an institution for the medical treatment of sick persons, as well as for ministering to their related needs. The statute expressly authorizes the formation of corporations for the "erection and maintenance of sanatoriums." Revised Statutes, art. 1302, subd. 6. Authority in such a corporation to provide medical treatment for patients, and to employ for that purpose persons duly licensed to practice medicine, is reasonably implied. It is true that article 742 of the Penal Code makes it a crime for any person to practice medicine without complying with the requirements prescribed in the Texas medical practice act. When those requirements are met, however, there is nothing in the statutes which implies a prohibition against a person so qualified engaging his services to another. In the present case, the Colgin Hospital and Clinic was vested with implied authority in performing its corporate functions with respect to supplying medical treatment to its patients, to employ persons qualified under the medical practice act to practice medicine. The commission of appeals, therefore, was of the opinion that the Hospital and Clinic could sue to collect its charges for professional medical and surgical attention rendered a patient.

In the absence of pleading and proof to the contrary, it is not to be presumed, said the commission, that any person

employed by the corporation as an instrumentality for supplying treatment practiced medicine without a license or that the corporation committed an unlawful act in that respect. Such a violation of law must be affirmatively pleaded and proved as a defense in order to be of avail. The commission, therefore, deemed it unnecessary for the plaintiff to allege and prove that its physicians who rendered professional services were licensed to practice medicine in Texas, in the absence of any pleading or proof on that subject on the part of the defendant.

The opinion of the commission of appeals was adopted by the Supreme Court—*Republic Reciprocal Ins Assn v Colgin Hospital & Clinic (Texas)*, 65 S W (2d) 286

**Medical Practice Acts Admissibility of Deposition in Revocation Proceedings**—Proceedings to revoke Moormeister's license to practice medicine for the alleged performance of a criminal abortion were instituted by the director of the department of registration of the state of Utah in January, 1930. At the hearing in March of that year the only evidence presented to show the commission of the abortion was the deposition of a woman patient of the physician, which was admitted in evidence over the physician's objections. Subsequent to the hearing, but before the director could revoke the physician's license, which he indicated he intended to do, the third district court, Salt Lake County, on petition by Moormeister, enjoined the director from revoking the license. The director then appealed to the Supreme Court of Utah.

The law setting forth the rights and duties of the department of registration (Chapter 130, Laws of Utah, 1921, as amended by chapter 49, Laws of Utah, 1923), said the Supreme Court, does not authorize the department to take or to use a deposition in a proceeding had before it. One section of that law (section 5, chapter 130, Laws of 1921) authorizes the director to administer oaths, conduct hearings and subpoena witnesses. It is well settled that the right to take a deposition in an action at law is entirely statutory and that statutes in derogation of common law are strictly construed. Consequently the authority of a court, board, commission or department to procure evidence by deposition, and to use the same, must be clearly conferred and authorized by statute. The power to issue a commission to take a deposition, or to use the same, is not implied from the power conferred on a board or commission to compel the attendance of and to examine witnesses. That the department in 1930 lacked this power was recognized by the legislature in 1933 when in adopting the Revised Statutes of 1933 it inserted in title 79, Department of Registration, chapter 1, section 30, a specific provision authorizing the department to take depositions. It follows, therefore, that there was no competent evidence adduced at the hearing on which the director could act.

The director contended that, notwithstanding the absence of competent evidence at the hearing, the district court was not warranted in affording injunctive relief because the physician had an adequate remedy at law, namely, an appeal from the order of revocation of the director to the district court, where a trial de novo could have been had. The physician contended, however, that the remedy by appeal is not plain, speedy and adequate. If the director, he argued, ordered his license revoked, his right to practice medicine would be suspended pending the outcome of an appeal which might take several years. In this way he would be deprived of a valuable property right and suffer irreparable injury. If the physician, said the court, were in fact deprived of his right to practice pending a final determination of the case, it unquestionably would justify a court of equity in granting injunctive relief. In *Baker v Department of Registration* 78 Utah 424, 3 P (2d) 1082, it was held that, in the absence of specific provisions in the medical practice act of Utah relating to appeals from orders entered by the department, an appeal may be taken to the district court where the case is tried de novo. The judgment of the lower court appealed from is vacated pending the determination of the appeal. In the present case, continued the court, Moormeister can, if and when the department revokes his license, serve notice of appeal on it, and the order of revocation will be automatically vacated. That being so, he will be free to practice his profession pending the outcome of the

appeal. Thus the court concluded that the physician had an adequate remedy at law by appeal and that the district court was without jurisdiction to enjoin the director, and ordered the injunction dissolved—*Moormeister v Golding, Director of Registration Department (Utah)*, 27 P (2d) 447

**Workmen's Compensation Acts Refusal to Undergo Operation**—If an employee receiving compensation for an injury sustained in the course of employment refuses to undergo a minor operation, simple, safe and reasonably certain to effect a cure, the continuing disability, said the Supreme Court of Nebraska, is to be considered as resulting from his own wilful act, and a suspension of compensation is warranted. Where, however, medical experts of similar skill and experience disagree as to the probable success of an operation, a refusal by an employee to submit to it is not unreasonable. What constitutes reasonable or unreasonable refusal on the part of an injured employee to submit to treatment, including minor surgical operations, is a question of fact to be determined from the evidence. The burden of proof is on the employer to prove that the tendered operation is simple, safe, and reasonably certain to effect a cure—*Sumnerman v Felthausen (Neb)*, 231 N W 831

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Toxic Symptoms of Methylene Blue**—Nadler and his associates observed that methylene blue has two actions. The first is the oxidation of hemoglobin to methemoglobin. The amount of methemoglobin found immediately following the injection of the average therapeutic dose is small. The second is that the drug used intravenously, excites the individual and by its rapid elimination into the stomach and urine produces transitory gastro-intestinal and urinary irritation. The most frequent toxic symptoms observed were restlessness, paresthesias, a sense of burning in the mouth and stomach, pain in the chest and strangury. These manifestations usually subsided in from twenty-four to forty-eight hours. Leakage of a small amount of methylene blue about the vein gives rise to painful infiltration. Electrocardiographic studies show that methylene blue produces a reduction in the height or even reversal of the T wave frequently with lowering of the R wave. This suggests depression of the ventricular musculature. The amount of methemoglobin found and the subsequent decrease in hemoglobin are not of sufficient magnitude to account for the clinical picture described on the basis of anoxemia. Therefore the indiscriminate use of methylene blue may produce unpleasant results and be dangerous to the patient.

**Iontophoresis of Acetyl-Beta-Methylcholine Chloride in Treatment of Arthritis**—Kovacs used a 1 per cent solution of acetyl beta-methylcholine chloride (1 Gm in 100 cc of water) in treating forty cases of chronic rheumatism sixteen of rheumatoid arthritis, fourteen of osteo-arthritis, three of bursitis, three of sciatica and four of neuritis. Reinforced asbestos fabric paper is saturated with the solution and wrapped round the affected joints. A fairly large malleable metal plate

is placed over the wet asbestos paper and connected to the positive pole of a galvanic generator. A dispersive, large, regular moist pad electrode is applied to the back or abdomen and is connected with the negative pole. The current is turned on and slowly increased to from 20 to 30 milliamperes, always being kept within comfortable toleration to the patient. Treatments of from twenty to thirty minutes are employed. The metal electrode or electrode clamps must not come in direct contact with the skin. Sweating was observed immediately after treatment and continues for from eight to ten hours. It is probably due to a direct action of the drug on the sweat glands or their nerve supply. The increased temperature of the skin was in cases in which a spasm of the peripheral blood supply was present. The increase of temperature varied from 4 to 10 degrees F and remained for from two to four hours. There was an increase of the rate of the capillary flow without enlargement of the capillaries. The visible capillaries did not increase in number after treatment. Slight redness of the skin was produced, which remained for from one and one-half to two hours and was due probably to the enlargement of the deeper small arteriole vessels. A questionable slight increase in the local leukocyte count was noted. A feeling of warmth of the treated part lasted from twenty-four to seventy-two hours, for longer periods after repeated treatments, and in some cases for a whole week. There was a reduction of the swelling, increased mobility and relief of pain. A general effect causing flushing, sweating, an increase of pulse rate and salivation, slight lowering of blood pressure and evidence of intestinal peristalsis was observed when large areas were treated. The most promising results were obtained in the most stubborn cases of rheumatoid arthritis, 95 per cent of the cases showed improvement. In the osteo-arthritic type the results were likewise encouraging, giving definite improvement in 80 per cent of the cases. There was full recovery in the three cases of sciatica, in which diathermy and galvanic treatment had failed to give relief. In the three cases of bursitis, two responded quickly but in the third case the treatment failed to give relief. The four cases of neuritis reacted well to the treatment and in every case there was a quick full recovery. In the few cases of peripheral vascular disease treated, desirable results have been obtained release of spasm with increased circulation.

**Correlation Between Pupillary Area and Retinal Sensibility**—The analysis of Luckiesh and Moss of the experimental data from fifteen subjects indicates that the variation in retinal sensibility between the subjects is of the same order as the variation in the areas of the natural pupils. It is also evident that pupillary area and retinal sensibility are opposing factors with respect to their possible influence on the level of illumination selected by an introspective appraisal of seeing. In general, the subjects with the larger pupils usually have the lower retinal sensibility, and vice versa. Differences in the size of the pupil and in retinal sensibility account only in part for the wide differences in levels of illumination selected as "desirable" by various subjects for a given critical visual test, such as reading. Apparently these differences are not due chiefly to physiologic factors associated with the visual sense.

**Variations in Fixation of the Cecocolon**—Kantor and Schechter believe that there is no need for operative intervention in atypical fixations of the colon except when actual evidence of intestinal obstruction is demonstrable. This would practically restrict such intervention to cases of volvulus and intussusception when excessive mobility is present and to cases of obstruction by bands when excessive fixation is present. The observation that hepatic flexure fixation is not associated with either gallbladder disease or gallbladder operations may be explained by the fact that in the majority of instances the fixation represents a congenital and not an acquired phenomenon. Similarly, the majority of cecal fixations may also be regarded as congenital rather than acquired in origin. The average vertical range of mobility of the hepatic flexure is  $1\frac{3}{4}$  inches. Normal variations in mobility range from more than 1 inch to less than 3 inches. The average vertical range of mobility of the cecum is  $1\frac{1}{2}$  inches. Normal variations range from 1 to  $2\frac{1}{2}$  inches. Hypermobility of the hepatic flexure may be said to exist when the vertical range is 3 inches or more, and hyperfixation when the vertical range is 1 inch or less. Hypermobility of the cecum may be said to exist when the vertical range is  $2\frac{1}{2}$  inches or more, and hyperfixation when the vertical range is 1 inch or less. The authors' study does not appear to reveal any marked clinical disturbances associated with the usual ranges of variations in fixation of the cecocolon as a whole, or of either of its terminations regarded separately. Such disturbances as are present seem to be adequately handled by the usual methods of conservative

medical management, such as are implied in the competent treatment of the unstable colon. In none of their cases did the authors recommend surgical therapy.

**Treatment of "Bleeding Nipple"**—Cutler points out that there is ample proof available that an adequate dose of radiation administered to a papilloma by interstitial treatment results in destruction of the lesion and its replacement by fibrous connective tissue, therefore he suggests the implantation of removable radium element needles for the treatment of selected patients suffering from a serous or serohemorrhagic discharge from the nipple. The method offers the advantage of avoiding the radical procedure of breast amputation for a lesion which may not be cancer and usually is not cancer when treatment is administered and which may possibly never become cancer. It is a more complete procedure than local excision, as it treats the entire duct system of the breast and at the same time avoids surgical intervention. It should be adequate to destroy completely a recent duct carcinoma, especially if it is unaccompanied by a palpable tumor. The author reports two cases of discharge from the nipple treated by the implantation of removable platinum radium needles. In both instances the discharge has stopped and there is no clinical evidence of disease after twenty-four and eighteen months, respectively.

**Phosphatase in Obstructive Jaundice**—Armstrong and his associates produced obstruction to the common bile duct in nineteen dogs and determined daily the serum phosphatase activity and bilirubin content. The serum phosphatase in every case rose to progressively higher values each day following the obstruction, reaching from thirty to a hundred times the initial amount after six days. In two cases the obstruction was later relieved and the animals were allowed to recover. The recovery period was accompanied by a fall in the serum phosphatase until the initial value had been reached. Gallbladder bile contains large amounts of phosphatase, while bile from a fistula has been noted to contain even greater amounts. Feces from the dogs before and after obstruction possessed great phosphatase activity. The authors observed daily five hospital cases of proved obstructive jaundice in regard to the serum phosphatase activity. During the development of jaundice the serum phosphatase increased from day to day, while during the subsidence of the jaundice the value diminished, although somewhat more irregularly. When the patient recovered it reached nearly the range given by normal persons. The height to which the phosphatase activity rose in the human cases was considerably less than that attained in dogs. Three cases of experimentally produced latent hemolytic jaundice in dogs and two cases of latent hemolytic jaundice in man were investigated. No appreciable rise was observed in serum phosphatase.

**Biology and Chemistry of Crystalline Lens**—Kirby and E-Wiener present a study of the development, growth and structural changes, chemistry and nutrition of the normal lens in its relation to the etiology of senile cataract, review analogous age changes in structure and chemistry of bradytropic tissue, and discuss the structural changes observed in senile cataract and the chemistry and nutrition of such lenses. The theory that considers senile cataract germ-plasmatically determined is elaborated on. Pathologic changes in the structural configuration of the lens protein molecules predispose to a lack of resistance of the lens as an organ, to changes in permeability, to changes in water binding power and to fatty degenerative phenomena of denaturation, coagulation and precipitation of lens protein and of inducing abnormal infiltration of fat and deposition of inorganic material. This hypothesis considers senile cataract to be a genetically induced change in the structural configuration of the lens protein molecule, which makes it susceptible to the physical and chemical phenomena concerned in the production of cataract.

Treatment of Postoperative Pain in Chronic Sinusitis by X Rays Kisch and R W A Salmund—p 464

**Malignant Tumor of Vocal Cord**—Baker and Lambert report a case in which a person, aged 59, complained of hoarseness for nine months, which became progressively worse after the onset. Laryngoscopic examination revealed a red sessile mulberry-like swelling occupying the greater part of the right vocal cord, with the exception of a free area at the anterior and posterior ends of the cord. The affected cord was still in motion on phonation. The general macroscopic impression of the tumor was benign rather than malignant. A portion of the growth was removed for biopsy. Histologic examination suggested that the tumor was a sarcoma, therefore it was decided to do a laryngofissure with excision of the affected cord. Unfortunately, the patient collapsed and died in the early stages of anesthesia before the operation could be commenced and no postmortem specimen was obtained. The sections examined showed a small nodule of tumor tissue measuring 6 by 3 mm. This was covered in part by stratified squamous epithelium. The examination of a section stained with hematoxylin and eosin showed, with the low power objective, numerous irregular, angular and spindle shaped cells lying in what appeared to be a fibrous tissue matrix. Among them occasional multinucleated giant cells were scattered. Most of the cells sent out processes, which merged with the general fibrillar matrix. The first impression produced by these appearances was that of a sarcoma. A more careful examination, however, led to the conclusion that the growth was in reality of epithelial origin, being perhaps best described as a polymorphic prickly cell carcinoma with spindle and giant cell formation.

systemic reaction to the infection could be demonstrated only by means of the precipitin and complement fixation reactions. In the absence of agglutination reactions it seems possible to the author that infection by *Shigella flexneri* may be more common than is supposed, because in most cases, if a positive agglutination has not been observed when the patient's serum is tested, the organism has been discounted as a possible pathogen. The author's patient gives a history of constipation and ill health prior to the development of her first symptoms, and therefore the suggestion that the constipation might be considered to be the primary cause of the invasion of the urinary system by organisms from the intestine might be put forward. The mode of infection of the urinary tract by organisms comparatively explained, but in the present case there is a proved invasion of the blood stream. The urinary symptoms antedated the symptoms usually associated with a bacteremia, but it has been shown that even *Shigella typhosa* can be isolated from the blood stream of contacts many days before the development of any clinical signs of the disease (Conradi). Therefore it might be postulated that the organisms in the author's case invaded the blood stream from the intestine, giving no symptoms until they attacked the urinary system.

Johns Hopkins Hospital Bulletin, Baltimore

- 54 383 466 (June) 1934  
\*Surgical Affections of the Pancreas Met with in the Johns Hopkins Hospital from 1889 to 1932 Including Report of Case of Adenoma of the Islands of Langerhans and Case of Pncreatolithiasis W F Rienhoff Jr and D Lewis Baltimore—p 386  
Alleged Toxicity of Cod Liver Oil W M Cox Jr and A J Roos Baltimore—p 430  
Occurrence of Cyclic Variations in Motor Activity in Relation to Menstrual Cycle in the Human Female E G Billings Baltimore—p 440

**Surgical Disorders of the Pancreas**—Rienhoff and Lewis summarize the results of 158 operative cases of pancreatic disease. Of the eighteen patients with acute pancreatitis, ten were well, one improved and seven died. Of the twenty patients with chronic pancreatitis, twelve were well, five improved and two were unimproved. One died and in this case death was due to a high intestinal obstruction, which had nothing to do with the operative procedure on the pancreas. In the carcinoma of the pancreas none of the patients were well, thirty-one were improved, thirty-nine were unimproved and thirty-nine died. Of the seven patients with pancreatic cysts, four were well and three were improved. Both patients who had pancreatic abscesses were well following operation. There was one case of pancreatic apoplexy and one of adenoma of the pancreas. Both patients succumbed to the operative procedure. The authors report a case in which a pancreatic stone produced first an acute hemorrhagic pancreatitis, to be followed a year later by a chronic pancreatitis. The stone was removed and the patient has remained well for a period of ten years.

**Alleged Toxicity of Cod Liver Oil**—Cox and Roos found no histologic evidence of any pathologic lesion in the hearts of rats fed for 130 days on a diet adequate in protein, salts and vitamins but containing 78 per cent of the calories as cod liver oil. The rate of growth of the rats so fed was definitely subnormal.

Cancer Survey of Kansas F L Reclor Evanson Ill—p 253

Examination of further sections stained by various methods has confirmed this diagnosis and has further elucidated the cellular detail of the tumor. The feature which, in hematoxylin and eosin stained sections, suggests that the epithelial origin of the tumor is the peculiar angular and "prickly" contour of the majority of the cells. This is well seen in some of the larger cells. An examination of sections stained by van Gieson's stain and Weigert's iron hematoxylin, and Mallory's connective tissue stain, reveals the fact that the fibrillar matrix of the tumor is composed of a true connective tissue forming in one part an intercellular network of five wavy fibers and in another more compact masses separating groups of epithelial cells, and a complex network of interlacing processes derived from the epithelial cells themselves.

\*Very Rare Case of Bancroftosis (Bancroft Filariasis) Summary and Conclusions H P Froes—p 183

**Rare Case of Bancroftosis**—Froes observed a case in which a Negro, aged 30, who was admitted to the hospital for cardiac disease, had suffered before from malarial attacks, and at the examination of his blood a small number of young schizonts of *Plasmodium falciparum* were detected. At the examination of blood taken at night some microfilarias were found which the author identified as embryos of *Wuchereria bancrofti*. Such embryos were detected again in the blood obtained at different times (night and day) and were most numerous between the hours 2 and 4 a m and 9 and 11 a m. Microfilarias were also found in ascitic fluid (obtained by puncture). The patient was suffering also from ascites (2 or 3 liters of fluid), 1,700 cc being removed by puncture. The microfilarias detected in this fluid—nonhemorrhagic and nonchylous—were embryos of *Wuchereria bancrofti*. The author considers the present case as one of latent filariasis, as no complaint, no lesion or symptom could be attributed with certainty to the parasite.

Contraction of Iris in Mental Disorders A Barbe—p 876

Is Tuberculosis Really Contagious? G Carbognin—p 877

**Acute Articular Rheumatism and Tuberculous Bacillema**—Meersseman and Lumaret, using the modified Lowenstein technic of blood culture described in the *Zentralblatt für Bakteriologie* (part 1, 120 127 [Feb 23] 1931), prepared 100 blood cultures of ninety-five rheumatic patients. Before taking this up, however, the authors used the same technic in thirteen confirmed tuberculous cases with only one positive result, in fifteen suspected tuberculous cases with entirely negative results and in six cases of erythema nodosum with negative results. Ninety-one of the ninety-five cases of articular rheumatism were of the acute or subacute type presenting the classic characteristics of Bouillaud's disease. There were one case of acute gonorrheal polyarticular rheumatism, two cases of clinically tuberculous rheumatism and one case of questionable syphilitic or tuberculous nature developing in a syphilitic patient. All these cases of Bouillaud's disease and the case of gonorrheal rheumatism gave negative results. The last three patients gave one positive and two doubtful results. The authors believe that the differences in results from those of Lowenstein are not assignable to technic alone but perhaps to a difference in clinical material. The authors' observations, however, give absolutely no argument in favor of the usual, frequent or even possible tuberculous etiology of Bouillaud's disease.

Relation Between Coracoiditis and the Sympathetic C Julliard—p 636

**Kyphoscoliosis and Spinal Cord**—Borchardt maintains that in severe kyphoscoliosis there occasionally occur mild root and compression manifestations. They are easily overlooked, because they usually disappear again without resort to therapeutic measures. Severe injuries of the spinal cord are rare. If they appear, it is usually during the growth period as "late injuries" in the form of transverse myelitis or, in exceptional cases, in the form of serous spinal meningitis. These two disturbances are the result of circulatory disturbances in the spinal cord or its meninges. However, the existence of a severe, congenital or rachitic kyphoscoliosis is of course no protection against other disturbances that, independent of the existing malformation of the vertebral column, may cause an injury of the spinal cord. In addition to myelodysplasia and other conditions, two cases are reported in which the disease of the spinal cord had no connection with the malformation of the vertebral column. One patient had an intradural extramedullary spinal tumor that, of course, had no connection with the deformity of the vertebral column. The other patient had a vertebral osteitis fibrosa osteoplastica with tumor and cyst formation, which led to a compression of the spinal cord. The author thinks that the compression had no connection with the existing kyphoscoliosis. So far it is unknown that a deformity of the vertebral column leads to softening or degeneration of the spinal cord but the author admits that it is not entirely impossible.

**Wound Closure in Garter Operations**—Capelle shows that the technic of garter operations has been perfected to such a degree that primary closure of the wound predominates. If drainage becomes necessary however, cosmetic demands and an effective drainage should not interfere with one another. The author suggests a method that combines the advantage of Kocher's incision and primary closure of the wound with improved discharge of the secretion by separating the opening for drainage from the surgical wound. He followed pointers

given by spondylitic abscesses of the cervical vertebral column. He found that they generally gravitate behind the sternocleidomastoid muscle toward the lateral cervical triangle and open outward in the region of the clavicular fossa beside the lateral rim of the sternocleidomastoid muscle. This space gives drainage possibilities also to the deeper portions of the goiter wound, as soon as the median cervical fascia has been opened toward it. Thus the drainage incision would be located below the external jugular, close to the outer rim of the clavicular insertion of the sternocleidomastoid muscle, in the cavity that lies between the insertion and the clavicle. In this region scars are less noticeable than on the anterior portion of the neck.

**Simulation of Hemopericardium by Traumatic Cardiac Dilatation**—Henschen reports an acute traumatic cardiac dilatation that developed following a gunshot injury of the thorax. Whereas the clinical examination indicated the presence of a pericardiac hematoma, the postmortem examination revealed intactness of the cardiac muscle and of the pericardium and the absence of a pericardiac effusion of blood. The simulation of a hemopericardium could therefore be explained only by an acute traumatic dilatation of the heart. Judging from the type, the author suspects an injury of the extracardiac nerve trunks or a concussion lateral action of the shot on the heart (sort of 'commotio cordis') or the two combined as the cause of the acute traumatic dilatation. He thinks that a reduction in the tonus by way of the nervous system may lead to a dilatation of the heart. He cites clinical and experimental observations indicating that atonic and myogenic dilatations may develop in the space of days, hours, or even in less than an hour (fifteen minutes or less). In the reported case the acute dilatation must have developed in the space of a few minutes. The author points out that Sauerbruch's statement to the effect that the hemocardium is clinically easily recognizable by the enormous widening of the cardiac dullness is not always true. On the one hand, the vertical shortening of the mediastinum produced by the elevation of the diaphragm and the transverse position of the heart connected therewith may indicate a hemopericardium as well as an acute cardiac dilatation. On the other hand, the acute traumatic cardiac dilatation may assume completely the character of a hemopericardium. Thus the surgeon enters the same misleading diagnostic paths as does the internist in the differential diagnosis of pericarditis and cardiac dilatation. The author thinks that, if the condition of the injured person permits, it would perhaps be possible to resort to the contrast visualization of the right heart by means of Forssmann's catheterization of the right auricle.

### Archivio Italiano di Chirurgia, Bologna

**Senile Involution of Mammary Gland and Cystic Fibrosis**—Gatta observed in a number of subjects that there is a gradual disappearance of fibrillary connective tissue, which is replaced by adipose tissue in senile involution. Fixed limits cannot be assigned to involution; it begins after the menopause and sometimes before it and is complete only in extreme old age. During involution at any age the parenchyma presents proliferations in addition to regressive processes. The proliferations are especially numerous immediately after the menopause. The dilatations of the alveoli and of the galactiferous ducts which take place in the breasts after the menopause are attributed to a direct activity of the epithelium and not to a sclerogenous action of the connective tissue. They must be distinguished from the cysts due to stasis, which are rare and often absent, their genesis being totally different. They are formed in great abundance immediately after the menopause and become less numerous with the progress of the involution of the gland until complete regression. The clear or eosinophilic cells are found in the female breast after the menopause; they are derived from the normal cells of the gland and repre-

sent their final stage. The aspect presented by the breast in its involution may be similar to that presented by cystic fibrosis. There are, however, always differences in the intensity of the proliferative processes, which allow for distinction between the two forms.

**Death from Intestinal Occlusion**—Chiariello conducted four series of experiments on dogs for the purpose of confirming the importance of the loss of gastro-intestinal juices in the pathogenesis of death from intestinal occlusion. In the first series, after having resected the jejunum at a suitable distance from the ligament of Treitz, the author injected into the distal opening fixed to the skin a 1 per cent solution of sodium chloride; he obtained thus a survival which in one case lasted fifty-one days. In the second series the saline solution was replaced by distilled water, but the survival has been minimal. In the third series the saline solution was administered intravenously but the survival was not as striking as in cases of the first series, in that it never exceeded fifteen days. In the fourth series the administration of a solution of dextrose gave a minimal survival. These experiments demonstrate that the cause of death lies in the loss of the gastro-intestinal secretions, which would produce an increase of the nitrogen elements of the blood, an expression of the disintegration of the protein substances, and that the administration of saline solution through an intestinal fistula succeeds in delaying death for some time.

### Beitrage zur Klinik der Tuberkulose, Berlin

85 172 (June 25) 1934

- Failures in Pneumothorax Therapy and Its Causes H. Mayrhofer —p. 57
- Evaluation of Serum Protein Fractions in Tuberculosis E. von Frolich —p. 64

**Blood Cholesterol in Pulmonary Tuberculosis**—It is shown by von Babarczy that the behavior of the cholesterol content in tuberculosis is determined by the activity of the process, by the allergy and by the degree of tissue disintegration. The activity of the tuberculous process is accompanied by a reduction in the cholesterol content of the blood. The increased allergy is accompanied also by a reduction in the cholesterol values. However, the increased tissue disintegration produces an increase in the cholesterol content of the blood. Thus the actual cholesterol content of the blood in pulmonary tuberculosis is determined by the activity and the allergy that effect a decrease, and by the tissue disintegration that produces the opposite effect, namely, an increase.

**Sero-Albuminous Expectoration Following Pleural Puncture**—Mumme describes the clinical aspects of sero-albuminous expectoration following pleural puncture. He rejects all pathogenic theories according to which the expectorate in sero-albuminous expectoration following pleural puncture is an expectorated pleural exudate. He maintains that the cause of sero-albuminous expectoration following pleural puncture is a local acute pulmonary edema, which develops in the prolongedly compressed and in the rapidly extended (during puncture) lung. Thus the expectorate is transudated blood serum. The development of the pulmonary edema following pleural puncture must be ascribed to degenerative changes on the capillary endothelium, also to mechanical and finally to angioneurotic factors. Epinephrine can prevent a sero-albuminous expectoration only when it is given early, that is, approximately fifteen minutes before the puncture is made. By introducing air into the pleural space and by thus renewing the pulmonary collapse, it proved possible to counteract a sero-albuminous expectoration and thereby save the patient. If in case of more extensive pleural punctures a part of the discharged fluid is replaced by air, the development of the pulmonary edema is prevented and with it also

the sero-albuminous exudation. The author rejects the puncture treatment of the serous "idiopathic" pleural exudates, because the measure does not reduce the duration of the disturbance. In "idiopathic" serous pleurisy, puncture should be resorted to only if, disregarding vital factors immediately following the discharge of the exudate, collapse treatment is instituted by inducing a pneumothorax.

### Munchener medizinische Wochenschrift, Munich

81 1003 1044 (July 6) 1934 Partial Index

- Prognosis of Complicated Deliveries and Its Consequences for the Physician H Guggisberg—p 1003  
 Treatment of External Eye Diseases A Siegrist—p 1006  
 \*Significance of Occurrence of Tubercle Bacilli in Urine of a Patient H Wildbolz—p 1012

 Status of Campaign Against Goiter in Switzerland F de Quervain—p 1020  
 \*Utilizability of Friction Method for Determination of Outlines of Organs A Bukovala—p 1026

**Significance of Tubercle Bacilli in Urine**—Wildbolz points out that formerly the presence of tubercle bacilli in the urine was considered indicative of a tuberculous disorder in the urogenital system. Some of the more recent investigations, however, have called the general validity of this rule into question. The author mentions several investigators who have reported cases of tuberculous bacilluria without the presence of tuberculous disease of the kidney. However, the majority of workers, studying the problem of tuberculous bacilluria, agree that, if it occurs at all, it is extraordinarily rare. The author states that the practitioner should assume the presence of a tuberculous disease of the urogenital organs when tubercle bacilli are found in the catheter urine. It is, of course, possible to mistake smegma bacilli for tubercle bacilli, but, if attention is given to the arrangement of the microorganisms, differentiation is readily possible, for the smegma bacilli are never close together but either are scattered or appear in loose groups. Moreover, they are generally shorter and plumper than the long and small tubercle bacilli. Because of their lipid covering, the tubercle bacilli are usually massed together. The presence of other signs of urogenital tuberculosis dispels the doubts about the nature of the acid-fast bacilli. Such signs are in men, infiltrations in the seminal vesicles and in the prostate or nodules in the epididymis, in women, infiltration of a ureter, which can be felt in the anterior vaginal vault. But, if in addition to the acid-fast bacilli no other tuberculous changes are demonstrable and a cystoscopic examination is not feasible, animal experiment should be resorted to. If the animals develop tuberculosis a urogenital tuberculosis can be assumed even if there are no other signs of tuberculosis, and the physician should see to it that the patient is subjected to a careful urologic examination. The good general condition and the absence of renal and vesical symptoms should not tempt the physician to regard the presence of tubercle bacilli in the urine as of minor importance, for not only is the patient in danger himself but he is also a danger to those who come in contact with him. The author maintains that the majority of patients whose urine contains tubercle bacilli have a caseous tuberculous lesion of the kidneys, genital tuberculosis being much less frequent. Since renal tuberculosis has only a slight tendency to scar formation, nonsurgical methods are of little avail, but surgical removal of the diseased kidney leads to complete cure in approximately 60 per cent of the cases. However, in some patients nephrectomy is contraindicated, this is the case particularly in bilateral tuberculosis, but even in unilateral renal tuberculosis nephrectomy may be inadvisable. Nonsurgical treatment should first be tried in all cases in which little or no pus is found in the urine and in which the function of the kidney is satisfactory.

**Disorders of Thyroid in Their Relations to Adjoining Organs**—Wegelin shows that the inflammatory diseases of the thyroid (acute and chronic thyroiditis, tuberculosis, lymphogranulomatosis) develop as a rule hematogenously but may lead to involvement of the neighboring organs. On the other hand in exceptional cases the changes may have an external origin, namely when the protecting wall of the thyroid capsule is perforated. In benign goiter there develop in addition to displacements and compressions of the neighboring organs also

adhesions with the larynx and the trachea. The author calls especial attention to the intralaryngotracheal goiter, in which the thyroid tissue grows even between the cartilages and underneath the mucous membrane of the larynx and the trachea. Malignant goiters frequently penetrate the capsule of the thyroid, but, on the other hand, the thyroid may be infiltrated and finally destroyed by neoplasms of the neighboring organs.

**Friction Method to Determine Outlines of Organs**—Bukovala recommends the friction method for determination of the outlines of organs whenever the more simple methods such as percussion, auscultation and palpation, fail. The stethoscope is placed with one hand on that region of the skin under which the organ is ordinarily found. At the same time the forefinger of the other hand makes scraping movements in a definite direction away from the stethoscope. On auscultation a scraping sound becomes perceptible. In order to exclude optic influences, the examiner should close his eyes. As soon as the friction reaches the point corresponding to the projection of the border of the organ on the skin, the auscultatory phenomenon disappears or changes in intensity and tone. If the same friction movements are made in various directions from the stethoscope, a number of points are detected the connection of which indicates the outline of the organ. The author recommends the friction method (1) for abdominal organs (liver, stomach and spleen), (2) for determining to what organs abdominal tumors belong and (3) for the determination of the lower limits of the heart.

 Report on Social Hygienic Investigation in Norrbotten and Västerbotten Districts Introductory Statement N Hellström—p 411  
 General Observations Concerning Care of Homes, Personal Hygiene, and So on G Ankarsward—p 418

**Treatment of Tuberculosis of Knee Joint**—In three fourths of Waldenström's twenty-five cases of microscopically established tuberculous synovitis treated during the last ten years, dropsy was noted at the outset. In five of the twenty-three cases treated conservatively from the start the treatment was completed, with good result in one case and a fairly good result in one case, in the seventeen, conservative treatment was discontinued and resection was done, in five cases after five years, in five cases after three years, and in eight cases after two years, with satisfactory ankylosis. Resection was done in two cases as soon as the tuberculosis was established. Because of the far longer and indefinite time required for conservative treatment, the far greater uncertainty as to the outcome, and the danger of recurrence in all these cases, the author advocates careful radical operation in every case of pathologically anatomically established tuberculosis of the knee joint in adults.

## THE IMPORTANCE OF THE STREPTOCOCCUS IN GENITO-URINARY DISEASES

CHAIRMAN'S ADDRESS

HARRY CULVER, MD  
CHICAGO

A casual understanding of the role of the streptococcus in genito-urinary diseases among any group interested in the clinical aspects will place its importance in widely varying spheres. Wrong conclusions, in this connection, can easily be made from one's own clinical experience. Without a careful search of the available sources of information and study of both the clinical and the experimental aspects of the subject, no measure of the role of the streptococcus in urology can be made.

With no thought of adding anything new to the subject, but for the purpose of directing attention briefly to the most important pertinent facts and probabilities, I open this subject of nonspecific infections of the urogenital tract.

Parks<sup>1</sup> says, "The group of bacteria known as streptococci is one of the most, if not the most important of the bacterial groups known to have a great influence upon man's welfare. Frequently there is not the sharp limitation of a streptococcus to a clinical disease as is the case with most other forms of bacteria. It seems as if the temporary adaptation of the organism to growth in a special tissue or tissues frequently determines its virulence and the localization of its growth."

In general, streptococci are found wherever man has been found and are essentially parasitic on an animal host. In a normal healthy man the surface of the mucous membranes of the nasopharynx, the crypts of tonsils, the intestine and the skin are normal habitats of various types of streptococci, each tissue harboring a preponderance of a certain type. Although the mucous membranes of the nasopharynx commonly contain green-producing streptococci, broadly speaking this variety is essentially intestinal, while the hemolytic type is confined to the upper respiratory tract, especially the tonsillar crypts. These potentially virulent organisms living a saprophytic existence have no influence on the welfare of the host until local or general tissue defense decreases, they may then invade the tissues of the host and produce the pathologic changes which their nature and the various tissue susceptibilities permit.

The genito-urinary tract, excepting the anterior urethra, is normally sterile. While the anterior urethra

harbors as saprophytes some thirty odd species of bacteria,<sup>2</sup> including several varieties of streptococci, this structure probably plays a minor role in the production of streptococcic infections of other urogenital organs.

The fact that streptococci are found on and in the healthy human body is not necessarily important if the normal defense mechanism remains intact, but, as Williams<sup>3</sup> states, if the local susceptibility is slightly greater or the coccus a little more poisonous there may be a slow growth of the cocci in the tissues with a slow cellular response resulting in a subacute or chronic infective focus or a focal infection. By some it is contended that a more or less continuous absorption of bacteria or their products from such a focus into the blood or lymph streams may result in subacute or chronic disease conditions in distant organs.

During acute local infections and, as some contend, also during subacute and chronic focal infections, some bacteria pass into the general circulation. Usually these invaders are rapidly removed from the circulation by the body cells, but repeated bacteremias, regardless of the number of available bacteria, in susceptible individuals may react eventually on special tissues.

An observation pertinent to the practice of urology was made by Hopkins and Parker,<sup>4</sup> who injected intravenously slightly virulent hemolytic streptococci into insusceptible animals (cats). They found that the bacteria quickly disappear from the blood stream and are found most numerous in the lungs, less in the liver and spleen, and still less in the bone marrow, lymph nodes, muscle and kidney. While not conclusive, it is at least suggestive that the kidney is a factor in removing virulent organisms from the circulation during transient bacteremias, making it a recipient of repeated attacks under the circumstances previously mentioned. Going further in clinical application, one finds that such attacks on kidney tissue previously abnormally susceptible, owing to malformation, malposition or disease, or, as held by some, to the presence of circulating streptococci with a special affinity for this tissue, furnish local conditions that may result in inflammatory processes of varying degrees.

Commonly, clinical bacteriologic studies of various urogenital infections place the streptococcus as a minor offender. There is very little doubt that it plays a much greater role when one considers the necessity for special cultural mediums, the inability to obtain cultures of some organisms under any circumstances, the overgrowth of more readily cultivable secondary organisms

<sup>1</sup> Parks, W. H. Introduction to Williams<sup>3</sup>.

and the technical experience necessary to cope with this problem

The studies of Young, Colston and Hill<sup>5</sup> are representative clinical observations. These workers recovered streptococci in 11 per cent of 600 cases of bladder infections. In slightly less than half of the cases the streptococci were in pure culture. The same relative proportion of streptococcal infections was found in the kidney specimens studied.

That the kidney has a special susceptibility for certain streptococci or their toxins, or both, has been recognized clinically as exemplified by the kidney complications of scarlet fever. It remained for Duval and Hibbard<sup>6</sup> to reproduce experimentally in rabbits, by the injection of a preparation of *Streptococcus scarlatinae*, a kidney lesion similar in many respects to that of acute scarlatinal nephritis in man. This observation constitutes evidence of a possible specific relationship of the streptococcus.

Bumpus and Meisser<sup>7</sup> did outstanding work, both clinical and experimental, in emphasizing the importance of streptococcus-harboring foci of infection and their relationship to certain instances of pyelonephritis. They point out that oral focal sepsis is a common associated lesion in patients with pyelonephritis and demonstrate the frequent selective action on the kidneys of streptococci removed from these foci. The common bacillary infections of the kidneys are presumed to be caused in most instances by secondary invaders. Rational treatment should be directed toward the primary cause as well as toward the secondary local infection. This presumption has been strengthened by the clinical observations of Cabot and Nesbit,<sup>8</sup> who found that early pure cocci infections of the kidneys were sometimes succeeded by a mixed infection with colon bacilli. Bumpus and Meisser observed that following the removal of a suspected focus there frequently would occur an exacerbation of the urinary symptoms accompanied by chills and a rapid rise in temperature. They considered this a favorable sign indicating that the causative focus had been removed. Following such reactions streptococci would appear, for a time, in the urine, which previously had apparently contained only colon bacilli.

Rosenow and Meisser<sup>9</sup> similarly demonstrated a relationship between experimentally infected devitalized teeth in dogs and various forms of nephritis, using streptococci having an elective affinity for kidney tissue. In similar experiments, infecting devitalized teeth of dogs with streptococci isolated from urine of patients with urinary stone, they found urinary stones in the dogs in the majority of cases. The streptococci were isolated from the kidneys, from some of the stones and from the teeth of the dogs. By a carefully controlled technic Eisenstaedt<sup>10</sup> found streptococci in the substance of kidney stones in 16 per cent of the stones studied.

Grulee and Gaarde<sup>11</sup> observed clinical instances of acute hemorrhagic nephritis in children from acute infections of the tonsils and nasopharynx. Hemolytic streptococci showing a great similarity to the organisms found in the throat were found in the urine in some instances.

The infrequently mentioned and less frequently diagnosed entity of renal infarction commonly, but not necessarily, secondary to endocarditis, is in a great majority of the properly studied instances, of streptococcal origin. Barney and Mintz,<sup>12</sup> in analyzing 143 such lesions, found the streptococcus in 72.7 per cent of the positive cases. Huggins<sup>13</sup> reports an instance of bilateral streptococcal renal infarction clinically cured by nephrectomy and subsequent drainage of the remaining kidney. There was no finding of endocarditis.

Falls<sup>14</sup> and his co-workers have found by tissue culture from the depths of the uterine cervical glands that the green-producing streptococcus was the predominating organism in most of the cases of endocervicitis studied. This is an important observation when considered in conjunction with the conclusion of Winsbury-White<sup>15</sup> that cystitis is a common companion of cervicitis, the bladder infection, localized at first to the region of the trigon, at least suggests a lymphatic connection between the cervix and the trigon. Certainly this combination of lesions is a common observation.

Submucous cystitis probably represents the lone streptococcal infection of the urogenital tract with more than presumptive evidence of specificity, with the possible exception of the orchitis of mumps. When not associated with ordinary cystitis, pure cultures of green-producing streptococci have been repeatedly recovered from the urine and from resected tissues. There can be little doubt from a clinical point of view that these lesions are metastatic and the well known experimental results of Bumpus and Meisser<sup>16</sup> add strength to this assumption. They injected nineteen animals with primary cultures from the teeth and tonsils of patients having submucous cystitis, sixteen of these animals developed lesions of the urinary tract, and in thirteen the lesions were in the urinary bladder. Only ten of 239 animals injected with streptococci from the teeth and tonsils of patients having diseases other than urinary infections developed lesions of the urinary tract.

Without bacteriologic facts to substantiate it but with pathologic observations to suggest it, Hunner<sup>17</sup> has indicated that streptococci from similar foci may produce ureteral lesions resulting in stricture. Probably the primary ureteral lesion is much more common than the resulting stenosis.

The anatomic situation of the prostate and seminal vesicles, together with their construction, make them especially susceptible to all types of infection. Herrold,<sup>18</sup> using special cultural methods, isolated streptococci in

34 per cent of 109 cases of chronic prostatitis and seminal vesiculitis, the types being equally divided between the hemolytic and green-producing organisms. He observed also a more pronounced and persistent lesion, as determined by palpation, than in the non-streptococcic lesions. All are familiar with the clinical frequency with which these structures become infected by metastases from distant foci, and more and more importance is being attached to these infections as a focus for further dissemination. Pelouze<sup>19</sup> states that so much attention is placed on certain primary areas of focal infection that other foci, though commonly secondary to them, and at times having a place of equal importance have been obscured. This is especially true of the prostate gland, which he believes is rarely a primary focus and that it cannot be cleared up as long as the primary focus remains. It is a common occurrence in large urologic wards to observe quite typical gonococcic infections of joints gradually assume the characteristics of streptococcic lesion and recovery cannot be expected until the various primary foci of infection, both streptococcic and gonococcic, have been eradicated.

Nickel<sup>20</sup> injected rabbits with green-producing streptococci isolated from infected prostates and seminal vesicles and found a marked tendency for them to localize in the tissues of the rabbits corresponding to the diseased tissue of the patients. Frequently the strains injected could be recovered from the experimental lesions in pure culture when often all other tissue cultures remained sterile. Obviously this important experimental result clearly points out the prostate and seminal vesicles as foci from which more generalized disease may originate.

In passing I shall only call attention to the specific streptococcic orchitis of mumps and postoperative erysipeloid infections.

Nonspecific infections of the urethra deserve more than passing attention at this time, owing to the vast number of intra-urethral manipulations being done. While streptococci are occasionally the predominating organisms in locally unprovoked nonspecific urethral infections, it is much more frequently the case following urethral trauma. This is especially so in long-continued trauma such as is obtained in indwelling urethral catheters. Nonspecific urethritis is the usual accompaniment of indwelling catheters. Cultural study of these infections shows an abnormally high incidence of streptococci as the predominating organism. The potential danger of this condition is obvious when followed by procedures such as transurethral vesical neck resections. Early in this work of resection I observed the most marked postoperative reactions following such local conditions. To obviate this danger I no longer prepare a patient for resection with an indwelling catheter for any extended period. In cases in which preparation is indicated, intermittent catheterization is done. If a considerable time for such preparation seems indicated a suprapubic cystostomy is much preferred, as a result of this practice I am now doing 20 per cent of all resections following cystostomy. Following the same line of thought the postoperative indwelling catheter carries a like danger and should be removed as soon as is consistent with local conditions.

It is logical to state that the streptococcus group of bacteria plays a really important role in the various phases of genito-urinary diseases. The presence of the organism is often not detected even in instances in which this is readily possible, and too frequently the significance is not properly interpreted. Although much effort has been expended in attempts to devise a specific chemical or biologic substance to attack these infections, nothing conclusive has resulted.

Much advance has been made in topical applications to local streptococcic infections, but this rarely has practical application in the practice of urology. The many researches in intravenous chemotherapy have emphasized the fact that it involves not only the direct effect on both parasite and host tissues but a number of indirect effects which may influence one way or another the curative results.<sup>21</sup> Most observers agree that with the exception of such diseases as syphilis there has been no evidence of satisfactory response to intravenous chemotherapy. The mechanism of immunity in these streptococcic endotoxic infections, as demonstrated by Gay,<sup>22</sup> depends chiefly on the large phagocytes of the reticulo-endothelial system. The opsonins in antisera aid some, but the large phagocytes must be present in sufficient numbers to complete a cure. The part that these large phagocytes play in local or tissue infections has received much attention from Besredka<sup>23</sup> and others and perhaps eventually something definite will result from the use of streptococcus antiviral and endotoxic vaccine, clinical investigation of which is now being carried out in various places. It is maintained by some, however, that such immunity is strictly local, at the site of the injection. Gay indicates that Besredka's results may be explained by the stimulating effect of certain nonspecific and even nonantigenic substances, such as plain broth, which, as he has shown, stimulate and collect the tissue macrophages in their vicinity. Regardless of this contention, there is very definite clinical evidence of a value, striking in some instances, of the intracutaneous injection of antiviral in other infections, notably gonococci. This method should not be eliminated on experimental data only and should be discarded in the treatment of the streptococcic infections only when found wanting after adequate clinical application.

When one appreciates that practically all of the streptococcic urogenital infections are secondary to some distant focus, usually in the head or the intestine, the first thought should be to eradicate the source of the infection before any hope of cure can be anticipated. Even though streptococci are not isolated from the urogenital lesion in certain persistent and recurrent urogenital infections, their presence as a primary and intermittent invader of these structures should be assumed and the patient should be treated accordingly.

THE PROBLEM OF ACCIDENTAL POISON-  
ING IN CHILDHOOD

JOHN AIKMAN, M.D  
ROCHESTER, N Y

Toxicology as it has been taught in medical schools has chiefly considered poisons in relation to homicide and suicide and as poisoning occurs in industrial medicine. Less attention is given to accidental poisonings. Textbooks on pediatrics have but little to say regarding accidental poisonings as a problem in diagnosis and treatment in children. Yet poisons are a real menace to the children of this country, as can be shown by hospital records and mortality statistics. These figures do not show nonfatal cases, those cases never seen by physicians, and those in which treatment was given but not placed on record. The experience of every pediatrician proves that poisonings are not infrequent in children. It is also obvious that such cases may not be recognized. Individual physicians see but few cases of any one poisoning, such as strychnine, but in the aggregate the cases amount to a total that goes far beyond that of diseases to which much more attention is given. The duration of symptoms in most cases is very brief, and records of the case are only those of the ambulance and coroner's office.

When the ever increasing number of poisons about the home and farm is considered it is not surprising that these tragedies occur, and it is evident that the problem will increase unless the attention of the profession and the public is directed along this line.

Accidental poisoning should be especially interesting to pediatricians because so many of these accidents occur in small children and because of the frequent difficulties in diagnosis, the high mortality from certain poisons, and the fact that children have a special susceptibility to certain poisons, such as opium and aniline.

Naturally, suicides are rare in childhood. Mortality statistics from the Bureau of Census for 1929 show but one suicide by poisoning (gas) under 10 years of age. Between 10 and 14 years of age this increases to thirty suicides.

A study of hospital records shows that poisoning due to drugs and poisons may be divided into two groups, those due to therapeutic accidents and those due to accidental ingestion of poisons. Out of 5 059 children admitted to the Strong Memorial Hospital in Rochester, forty-seven instances of poisoning were recorded. Of these, twelve were due to accidental poisoning by drugs, eight from food poisoning, and six from mushroom poisoning, and twenty-one were classified as therapeutic accidents. The latter were chiefly dermatitis medicamentosa due to phenobarbital, bromides and the like.

The accidents that occur in the treatment of disease are largely due to an idiosyncrasy or sensitivity that patients have to certain drugs. But other more serious accidents may occur, such as the administration of boric acid solution in place of saline solution by mouth or subcutaneously, also the administration of adult sized preoperative hypodermic injections to children.

Mortality statistics for 1929 show that 530 deaths from acute poisonings (gas excepted) occurred in the United States in children under 5 years of age, while only forty-seven instances were reported in children aged from 5 to 9 years. During the second year of life

260 deaths occurred, and during the third year 118. As might be expected, the small child just able to walk and get into things is the most frequent innocent victim, usually of some one's carelessness. When uncertainty exists as to diagnosis in children attacked with profound illness, the question of accidental poisoning must always be seriously considered. This is especially true if several members of the family have the same symptoms.

Poisonings have been confused with perforation or rupture of an abdominal viscus, general convulsions of gastro-intestinal or other origin, diabetes, nephritis, severe gastro-enteritis and the like.

TABLE 1—*Fatal Poisonings of Children Five Years of Age and Under in New York State (Exclusive of New York City) from 1926 to 1932*

Kind of Poison	1926	1927	1928	1929	1930	1931	1932

Whisky						1	
Wood alcohol					1		
Zinc stearate				2			
Total	26	27	27	23	23	24	8

The symptoms produced by certain drugs also cause problems in diagnosis and treatment. The disturbances in body temperature, flushing of the skin and increased respiratory or pulse rates produced by atropine have caused confusion. The extreme cyanosis seen in shoe dye poisoning from nitrobenzene or in aniline poisoning occurring from ink used in marking diapers may be puzzling. The serious symptoms that may be produced in small infants by the use of mentholated nose drops and also the serious consequences following the inhalation of zinc stearate powder are both pediatric problems. The fact that bismuth subnitrate can produce nitrite poisoning must be kept in mind when a bismuth compound is prescribed for children.

Table 1 shows the deaths from accidental poisonings of children 5 years of age and under in New York State (exclusive of greater New York) classified under the international list number 177. These figures were

furnished by the New York State Department of Health. The poisons are recorded as they appeared on the death certificates and are not always clear and convincing. The table shows the wide range of poisons taken and also that certain poisons claim victims each year, poisoning due to arsenic from rat pastes, phosphorus or mercury poisoning from fireworks, lye kerosene, cresol poisoning and lastly that ever present group due to strychnine. Strychnine poisoning<sup>1</sup> is chiefly due to brightly colored sugar-coated cathartic and tonic pills, such as A B & S, A B S & C and Hinckle's Cascara. These tablets sold over the drug counters without warning as to their danger cause more deaths than any other poison.

The one favorable showing in table 1 is for strychnine poisoning, which shows a considerable reduction. This must be due to improved treatment although I would like to think that increased knowledge regarding this hazard has reduced the actual number of these accidents. One also wonders whether persons with chronic constipation have been influenced by high pressure radio and newspaper advertisements of saline and phenolphthalein cathartics to change from the older

Table 5 lists commonly used preparations containing poison substances which may be found about the home. The acids and alkalis contained in these articles come under the federal Caustic Poison Act, which requires, if the poison is used in or over a specified percentage,

that poison labels and directions for treatment be placed on containers. Similar legislation should cover more of the poison articles about the home.

The public must first be informed that the articles contain poisons and then that unused medicines and poisons should either be destroyed or be kept away from children. Both the public and the profession must consider poison cases more seriously.

Treatment, especially stomach washing, should be instituted whenever suspicion of poisoning exists. Patients have died while speculation was going on as to diagnosis and treatment. More attention should be given to this subject in medical schools and hospitals and especially in the children's departments.

Emergency departments should be equipped for adequate treatment. An easily accessible outline of accepted methods of treatment should be available.

household remedies such as Hinckle's Cascara and A B & S pills.

Table 2 lists some of the poisons to be found in insecticides, rodenticides and fireworks. Many instances are found in which whole families have been poisoned by mistaking an insect powder for a food ingredient or in which children have eaten preparations put out for rats.

Arsenic, sodium fluoride, nicotine, thallium and hydrocyanic acid, mercury and phosphorus are dangerous poisons and have all caused deaths of children.

The materials used in the painting trade contain many dangerous poisons. The widespread use of paints in the home results in many cases of poisoning. The habit of eating paint from cribs and toys has also caused much poisoning. Table 3 shows some of the poisons found in this group.

Many cosmetic preparations contain poisons and, as they do not come under the pure food laws, may have no warning on the label. The ingredients of these preparations are discussed in "Cosmetics and Allied Preparations," issued by the American Medical Association. There have been few deaths reported from cosmetics except in Japan, where many fatalities have occurred from lead in face powders.

Therapeutic accidents can be prevented by better written instructions and by more careful supervision of inexperienced interns and nurses. Parents must be warned when dangerous drugs are prescribed. Special safeguards must be thrown about all hypodermic subcutaneous and intravenous medications.

Medical science, having already reduced to a large degree the mortality rates in many childhood diseases, is looking for new fields in which advance can still be made. It seems to me that the profession and especially this section will find the problem here presented as worthy of its attention.

## SUMMARY

1 Too little attention is given to accidental poisoning as it occurs in children

2 More than 500 deaths from acute poisonings (gas excepted) occur yearly in the United States in children under 5 years of age. Practically one half of these occur during the second year of life and one fifth during the third year.

3 Poisoning presents special problems as to diagnosis and may be overlooked.

4 Strychnine poisoning due to brightly colored sugar-coated cathartic and tonic tablets causes more deaths in children than any other poison.

5 In order to reduce these accidents the public must be informed of the dangers of poisons kept within reach of children.

6 The contents of articles containing poisons should be placed on packages and poison labels required by law.

7 Better instructions regarding accidental poisoning should be given in medical schools and hospitals.

184 Alexander Street

## ABSTRACT OF DISCUSSION

DR S W CLAUSEN, Rochester, N Y. Dr Aikman's contribution demonstrates that physicians have much to do in preventing death from accidental poisoning. In the training of medical students, toxicology has been slighted in some schools. Whether or not this subject is taught in preclinical years, the responsibility for instruction in practical toxicology rests on the clinical teachers. We include in our final examinations in pediatrics a question on the source, symptoms and treatment of the commoner poisonings in children. We also provide in our emergency department copies of the Outline of Symptoms and Treatment of Poisoning by Hanzlik and Leake. To teach the prevention of poisoning, we insist that wherever possible active poisons be not prescribed where less active poisons or nontoxic substances will suffice. For example, in the treatment of ammonia dermatitis (diaper rash), we prescribe a diaper rinse of boric acid, instead of one of mercuric chloride. To keep poisons away from children, it might be wise for the physician occasionally to inspect the family medicine cabinet. Difficult as it is to interest medical students in legal matters, an effort should be made in our schools to promote interest in legislation designed to enforce proper labeling of dangerous articles, such as lye, ammonia and insecticides, and to regulate the sale directly to the public of poisonous proprietary medicines and cosmetics.

DR C W WICKOFF, Cleveland. I have had only two cases of aloin, belladonna and strychnine tablet poisoning. One patient died in strychnine convulsions, and the poisoning of the other was discovered in sufficient time to allow early and effective lavage, so that the child had only a slight increase in muscle tonicity and an enteritis. Proprietary phenolphthalein tablets are the most commonly selected by children. The color is attractive and the odor and taste are pleasant. This past winter such a case was reported in THE JOURNAL. The child died in convulsions. Fortunately, zinc stearate powder inhalation pneumonias have been greatly decreased in the last few years because of the educational efforts of pediatricians and the manufacturers arranging a spring slide top on the container. Boric acid poisoning is not uncommon. The pound package is nearly identical with that of lactose. Others are corrosive mercuric chloride tablets, selected by children because of the attractive blue color, also tincture of iodine used in place of mild silver protein because of the similarity in the size of the bottle and the color of the contents. I believe that all physicians should make it a routine practice to caution emphatically the parents of runabouts and older children as to the dire results of accidental drug and chemical poisoning, and that all medicines and household chemicals should be kept in a locked cabinet out of the reach of children. This section might go on record as recommending to the Council on Pharmacy and Chemistry and the Bureau of Investigation and to the American Academy of Pediatrics that immediate and definite action be taken with the manufacturers, wholesalers and retailers in regard to the contents and labels and containers of all the more commonly used drugs and chemicals, and that physicians be instructed to caution parents.

DR JOHN AIKMAN, Rochester, N Y. It is important that the public be informed regarding the hazards of poisoning. Proper legislation also will reduce these accidents. I attempted to get some action on strychnine poisoning three years ago and there was one editorial written which promised support, but little has been done. Children make a great effort to get into poisons. They go out of their way to get them. I had the experience one hot Sunday last summer of having to wash out the stomach of a five-year-old boy who had eaten a whole package of En-lax tablets that he had taken from a locked

bureau drawer The chief danger comes from strychnine and the other pills disguised with sugar coating The bright color of the sugar coating imitates candies I think it is a very vicious thing to have tablets and medicines that imitate candy, because they make a dangerous trap for the innocent child One wonders how much the pediatricians need to use strychnine It has been shown quite definitely that strychnine in the cathartic tablet is not necessary It is simply a shotgun prescription handed down from years back It would be quite a job to get the manufacturers to reduce the sale of such tablets unless they can see that some other cathartic will sell better

## CARBON MONOXIDE POISONING

HARRISON S. MARTLAND, MD

NEWARK, N. J.

Highway accidents and asphyxiations from carbon monoxide greatly exceed all other forms of violent death and the investigation of such deaths constitutes a very large and important part of the medical examiner's work.

It is now a well known fact that in the United States the automobile causes about 30,000 deaths a year and injures close to a million, with a resultant cost of many billion dollars per year Furthermore, in the last five years little has been accomplished in the prevention of such accidents

The total number of deaths from carbon monoxide is more difficult to estimate, since, in many localities, bureaus of vital statistics and departments of health separate suicidal from accidental asphyxiations Further, the very low ebb to which forensic medicine has sunk in this country, owing to an ancient, politically bad coroner's system, renders investigations inaccurate and often of no value

It may be roughly assumed, however, that there are 50,000 asphyxial deaths a year in this country, approximately 1,000 every week, and that about one half of them are caused by carbon monoxide

In New York City, where the population is about 7,000,000, statistics are of real value, since all such deaths are reported to and investigated by the office of the chief medical examiner

During a five year period (1928-1932) there were 5,289 deaths from carbon monoxide poisoning, an average of over 1,000 deaths a year, as shown in the accompanying table As a cause of violent death it is exceeded only by highway accidents, which, for the same period, averaged 1,400 a year

Certainly more than half of such deaths throughout the country are accidental and due, on the one hand, to such factors as faulty and leaky gas fixtures, carelessness and intoxication, and, on the other, to a lack of interest on the part of the public, the hospital authorities and the medical profession in quick, competent resuscitation methods

### THREE MAIN SOURCES OF CARBON MONOXIDE POISONING IN CIVIL LIFE

In civil life by far the most common source of danger is the inhalation of illuminating gas In 5,289 deaths from carbon monoxide in New York City, 5,090 were

caused by illuminating gas, 102 by automobile exhaust, 74 by coal gas and 23 from all other sources

**Illuminating or City Gas**—Illuminating gas, as now used, is a mixture of "coal gas" made by the destructive distillation of coal, containing about 7 per cent of carbon monoxide, and "water gas" made by blowing steam through hot coal and containing about from 40 to 50 per cent of carbon monoxide This mixture contains usually about 20 per cent of carbon monoxide Illuminating gas composed chiefly of coal gas contains much less carbon monoxide and is distinctly less dangerous

**Exhaust Gas**—Exhaust gas contains the products of combustion escaping from the exhaust pipes of automobiles, motor boats and airplanes These vehicles are all run by engines of the internal combustion type, in which the explosion within the cylinders occurs in the presence of gasoline containing 85 per cent carbon and 15 per cent hydrogen and air containing 80 per cent nitrogen and 20 per cent oxygen Theoretically a motor operating with 100 per cent efficiency would present no carbon monoxide in the exhaust However, since this is impracticable, the gas is present in direct proportion to the inefficiency of the engine In an average rich mixture the carbon monoxide content may reach as high as 7 per cent, in leaner mixtures it is proportionately less

Henderson<sup>1</sup> has shown that the average car in a small one-car garage will raise the carbon monoxide content of the air in five minutes to 0.25 per cent, which is not only enough to paralyze a man in a few minutes but to cause death if preventive measures are not taken quickly If the engine is raced, so frequently the modus operandi of suicides, death will ensue with extreme celerity

**Coal Gas**—Coal gas contains carbon monoxide that escapes into the air from the improper combustion in any stove or apparatus which burns coal, wood, charcoal or coke It is especially apt to be present in banked coal fires, in which the air supply has been checked and a top layer of fresh coal has been added Carbon monoxide again is formed in the top coal layers, where it may be seen burning with a pale blue flame above the layer of black coal Much of the carbon monoxide escapes into the air and in the event of ill fitting flues the house to a greater or less extent becomes permeated The recent tragedy among the Dartmouth students occurred in such a manner following the insidious escape of gas throughout the night into the sleeping rooms Because of the extreme cold weather, all the windows had been closed

### OTHER MORE UNUSUAL SOURCES OF CARBON MONOXIDE POISONING

Improper combustion in any apparatus burning coal, wood, oil, gas, charcoal or coke, or in conflagrations and smoke, may occasionally be responsible for asphyxial death

Inefficient exhaust pipes may lead carbon monoxide into the cockpit of an airplane in amounts sufficient to affect the pilot

Sailors entering "blisters" (the false, external hulls of battleships, designed for torpedo defense) or submarine pontoons (metal drums used for raising sunken submarines) may be overcome and occasionally are killed by carbon monoxide

<sup>1</sup> Henderson, Yandell. The Dangers of Carbon Monoxide Poisoning and Measures to Lessen These Dangers. Report I of the Committee on Poisonous Gases. J. A. M. A. 94: 179-185 (Jan. 18) 1930

Read before the Section on Miscellaneous Topics, Session on Forensic Medicine at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934  
From the office of the Chief Medical Examiner of Essex County (Newark), N. J., and the Department of Forensic Medicine, New York University and Bellevue Hospital Medical College

In times of war, asphyxial deaths due to carbon monoxide may occur in turrets filled with explosive gases from recoiling guns, machine gun pits, tanks, engine rooms of small war craft, and with the bursting of high explosives

#### SINGLE EXPOSURE TO LETHAL AMOUNTS

*Suicidal Asphyxiations*—The inhalation of illuminating gas is the most common method of committing suicide in the majority of civilized countries, because of its accessibility, cheapness and supposed freedom from pain

In my district nearly one half of the suicides are executed in this manner, other methods of suicide, in the order of frequency being hanging, jumping from buildings, shooting, poisoning, cutting, stabbing and drowning

The number of suicidal asphyxiations from carbon monoxide would be much larger if many probable suicides were included which, because of a reasonable doubt or from lack of proof, had to be classified as accidental

*Deaths from Carbon Monoxide Investigated by Chief Medical Examiner of New York City for Five Year Period 1928-1932*

Year	Derived from Illuminating Gas			Derived from Automobile Exhaust			Derived from Coal Gas			Unusual Sources
	Accidental	Suicidal	Homicidal	Accidental	Suicidal	Homicidal	Accidental	Suicidal	Homicidal	
1928	567	520	3	12	1	0	14	0	0	1
1929	502	582	11	14	0	0	17	0	0	6
1930	413	616	13	12	1	0	22	0	0	1
1931	293	636	12	16	6	0	10	0	0	3
1932	262	649	6	25	15	0	11	0	0	12
Total	2,042	3,003	45	79	23	0	74	0	0	23
Grand total	5,289									

In New York City of 7,219 consecutive suicides reported to the Medical Examiner's Office, 3,003, or 41 per cent, were accomplished by illuminating gas, eight by automobile exhaust and none by coal gas. The small number of automobile exhaust cases may well be explained by the relative scarcity of one car garages and the great difficulty in deciding whether death was suicidal or accidental. Since there has been considerable publicity concerning the danger of running a motor in small garages, it is my opinion that most asphyxiations by automobile exhaust are suicidal in nature. In no other form of suicide can the circumstances of an accident be so closely mimicked as in the individual garage cases. Often the reliance of an astute insurance company clarifies the case when the question of payment of a double indemnity accident policy is later raised.

The suicides from illuminating gas are performed in a great variety of ways, some by turning on gas fixtures and flooding the room with gas, some by placing such instruments as paper cones and flexible hoses with or without funnels in or near the mouth, and others by leaning over gas ranges and ovens. Regardless of the method, the effect is due to unburned gas in the inhaled air.

Resuscitation methods are of little avail in most of these cases, since a suicide usually performs the act secretly and without publicity. Rigor mortis is often present when the body is discovered.

*Accidental Asphyxiations*—Likewise, nearly one half of all accidental asphyxiations are caused by carbon monoxide, the remainder consisting chiefly of accidental asphyxiation due to drowning and a miscellaneous group comprising asphyxia in the new-born from such causes as overlying, smothering, postural asphyxiations and aspiration of vomitus.

In 4,677 accidental asphyxiations in New York City in a five-year period (1928-1932), 2,222, or 47 per cent, were by carbon monoxide. The carbon monoxide was from illuminating gas in 2,069 cases, from auto exhaust in 79 cases and from coal gas in 74 cases.

Accidental asphyxiations by carbon monoxide are due to a great variety of causes, the most of which are such conditions as faulty and leaky gas fixtures, flexible and worn out gas hose, carelessness, intoxication, tripping over and disconnecting a gas hose, pots boiling over and putting out a gas fire, hot water heaters and stoves without flues and quarter meters. There is practically always a direct escape of unburned gas into the surrounding air.

Furthermore, in gas stoves and water heaters it must not be forgotten that carbon monoxide may escape into the air with every hole of the burner lit. The chilling of the flame when it comes into contact with a cooking utensil or pipe containing cold water may stop the combustion at its first stage and large amounts of carbon monoxide may escape, producing low grade intoxication characterized by such symptoms as headaches and occasionally in closed rooms may cause a gradual building up of carboxyhemoglobin in amounts sufficient to produce death. To avoid this, cooking utensils and water pipes should be just above, not in, the visible flame.

In a somewhat similar manner incomplete combustion in hot water heaters without flues may occur with the escape of carbon monoxide directly into the room.

It is in this group of cases that the greatest opportunity is offered for resuscitation by means of artificial respiration and the inhalationary treatment, since they are often found shortly after the onset of asphyxiation.

It is in these accidental asphyxiations that the most important role is played by preventive measures, such as education of the public regarding daily hazards of carbon monoxide, abolition of badly designed stoves, flexible tubing, quarter meters and similar apparatus, efficient inspection, supervision and control of household fixtures made necessary by the increasing use of gas for heating purposes, constant warning against the danger of starting cars in small, closed garages, and proper ventilation and health regulations for workers in large garages, with the possible use of flexible exhaust tubes on cars being repaired. Since all these precautions have been described in a classic manner by Henderson,<sup>1</sup> it is only necessary to enumerate the most important here.

Henderson further believes that a reduction in the amount of carbon monoxide in illuminating gas is desirable and if it could be cut to one half without increasing the price it would greatly reduce accidental asphyxiations. The discovery of a less poisonous gas should be financially encouraged.

*Homicidal Asphyxiations*—Committing murder by turning on the gas is not common, but it occurs with sufficient frequency to warn the medical examiner not to dispose of gas cases quickly and carelessly, without careful investigations.

Most of the homicides by gas in my experience have been caused by a person committing suicide who kills another person at the same time, either accidentally or with homicidal intent.

In New York City during this five-year period forty-five homicides were accomplished by illuminating gas.

#### RESULTS OF THE MEDICAL EXAMINER'S STUDY IN CARBON MONOXIDE DEATHS

It is of prime importance, from scientific, therapeutic and medicolegal aspects, to recognize two main groups of cases: (1) bodies found dead as the result of carbon monoxide from illuminating gas, automobile exhaust, coal gas or other more unusual forms of carbon monoxide asphyxiation, (2) persons resuscitated so that respiration is restored and carbon monoxide eliminated but who never regain consciousness and die in coma from one to three days later or occasionally recover.

**1 Examination of the Body**—In bodies found dead as the result of carbon monoxide or in bodies of individuals dying a very short time after exposure, the most important and characteristic finding is the bright pink color of the skin and the postmortem lividity. This color is distinctive and not seen to such an extent in any other form of death. The face often appears natural, as if alive. Occasionally a similar color, although rarely so pronounced, may be seen in bodies exposed to extreme cold or following the ingestion of cyanide.

If the body is found lying on the back, this color will be most pronounced over the posterior parts. If the body is lying face down, the bright red lividity will be noted over the ventral surface and will shift in a short time to dependent parts if the body is turned over, provided the blood is still confined to the capillaries and postmortem decomposition has not set in.

It is important that physicians, especially ambulance surgeons, should recognize this typical color in gas poisoning and report all such cases immediately to the medical examiner.

If the medical examiner is satisfied as to the cause of death and contemplates releasing the body for burial without an autopsy, it is often wise to obtain a specimen of blood for the toxicologist by aspiration from the heart. The toxicologic examination of the blood often settles any argument as to the cause of death.

If such a body is exhumed several months or even years after death, carboxyhemoglobin may still be detected in the blood or in extracts of the organs, although the amount of saturation cannot be quantitatively estimated.

Usually the body of an individual killed by carbon monoxide remains in a state of good preservation, but I have occasionally seen instances in which the postmortem decomposition was very rapid.

**Autopsy**—At the autopsy of a body found dead from carbon monoxide or of an individual dying shortly after exposure, the outstanding finding is the bright pink to cherry red of the blood and all blood-containing organs. When the body is opened this color is so pronounced that it is characteristic of carbon monoxide poisoning. The right heart and large veins of the mediastinum are distended with bright red fluid blood containing no clots. The muscles, stomach, intestine, liver, kidneys and brain all show this same bright pink.

Other characteristic changes often present are pulmonary edema with bright pink foam in the air passages and cerebral hyperemia and edema. The cerebral arteri-

oles, capillaries and venules are frequently distended as in an injection preparation. Petechial hemorrhages occur sometimes, especially in the subcortical white matter.

**2 Clinical Course**—If breathing has been restored by artificial respiration and inhalational treatment, such as the administration of carbon dioxide and oxygen, carbon monoxide is almost entirely eliminated in a few hours and an examination of the blood for carboxyhemoglobin in amounts known to be toxic will often be negative.

The patient, however, may remain comatose and die in from one to three days or longer without regaining consciousness. Often in these cases futile attempts are made to save the victim, such as the giving of blood transfusions and methylene blue.

Occasionally the victim eventually recovers completely. Others may develop later some form of psychosis, or even idiocy. Postasphyxial encephalitic syndromes are more apt to occur in cases in which the original period of anoxemia has been a long one and inhalational treatment for quick elimination of carbon monoxide has not been used.

**Autopsy**—In the cases which result in death all chemical and spectroscopic tests for carboxyhemoglobin are negative. The correct diagnosis rests on the history of the case and the finding of bilateral degeneration in the globus pallidus of the lenticular nuclei (Kolisko's lesion), together with edema of the pia-arachnoid and parenchyma of the brain.

These bilateral areas of softening are usually from 1 to 2 cm in diameter, elongated, brownish, and grossly resemble areas of thrombotic softening. They are caused during the period of asphyxia by the resultant anoxemia. Their peculiar location has been thought by some to be determined by the sharp right angle made by the nutrient arteries supplying this portion of the brain and the increased tendency to thrombosis in carbon monoxide poisoning. They are seen best about the third day after asphyxiation.

Freeman,<sup>2</sup> who has studied these lesions histologically, states that the process begins with a rather selective anemic necrosis of the anterior portion of the pallidum, which soon breaks down and becomes infiltrated with blood. Leukocytes may be found in considerable numbers about the walls of the necrotic vessels. The main processes seem to be autolysis, fatty degeneration and necrosis.

In two of my recent cases, in which intravenous injections of methylene blue were given, typical bilateral areas of softening of the lenticular nucleus were found. On exposure to the air they turned a distinct blue, the rest of the brain remaining normal in appearance. This is a beautiful example and confirms the work of Burrows<sup>3</sup> on the localization in inflammatory areas of certain dyes injected into the blood stream. The other organs which showed discoloration by the methylene blue were those chiefly involved in its elimination, i.e., the bladder, which was a deep blue, kidney pelves, ureters, mucosa of the stomach, colon and gallbladder which became bluish on exposure to the air.

Patients with these lesions often recover. Old healed cystic areas may sometimes be seen in patients dying from other causes years after exposure to carbon

<sup>2</sup> Freeman, Walter. *Neuropathology*. Philadelphia: W. B. Saunders Company, 1933. p. 239.  
<sup>3</sup> Burrows, Harold. *Some Factors in Localization of Disease in the Body*. London: Baillière, Tindall & Cox, 1932.

monoxide. The degenerated material has been taken up by microglia cells that have become ballooned with fat, pigment and iron. Cyst formation with connective tissue overgrowth and encrusted vessels is the common end stage.

In addition, other parts of the brain may be similarly affected, particularly the subcortical white matter and the putamen. Rarely are these areas visible to the naked eye, and precise methods of neuropathology are necessary to demonstrate them. Freeman<sup>2</sup> states that sometimes the diffuse fibrosis with marked formation of new capillaries may lead to gross deformity of the cortical architecture.

I had an opportunity recently of examining sections from the cerebral cortex of a patient who, during a tonsil operation, stopped breathing for several minutes, respirations were subsequently restored, but the patient never regained consciousness and died the next day. Extensive central chromatolysis of the neurons in the deep layers of the cortex with vacuolated cytoplasm and even ruptures of the cell membranes were found, clearly demonstrating the disastrous effect of prolonged anoxemia on the brain. This lesion would have been entirely missed and the cause of death not clearly established except for careful histologic studies.

Likewise in many cases of carbon monoxide poisoning the damage to the brain is more diffuse and extensive than the gross focal lesions in the corpora striata would lead one to believe. Only careful histologic study will detect the extent of the damage done.

Such lesions undoubtedly account for the psychosis, and in some cases imbecility, following carbon monoxide asphyxiation. It is interesting to note, however, that the parkinsonian syndrome rarely occurs in these cases, in spite of the location of the gross lesions, suggesting that there is something more to the syndrome of paralysis agitans than a focal lesion in the globus pallidus.

#### RESULTS OF TOXICOLOGIC EXAMINATION

While the external appearance of the body together with the results of the autopsy are usually conclusive in carbon monoxide deaths, this evidence should be supported in a routine way whenever possible by spectroscopic and chemical examinations of the blood for carboxyhemoglobin.

Samples of blood for the toxicologist should be taken from the heart chambers or from the interior of the body, since samples from the superficial veins might show traces of carboxyhemoglobin in a body that was dead before it was exposed to carbon monoxide. The blood should be placed in small vials, filled to the top and tightly corked. Properly preserved specimens may be kept for years. The toxicologist Gettler has one in his laboratory taken over twenty-nine years ago which still shows carboxyhemoglobin.

In exhumed bodies, blood may sometimes be obtained either from the cerebral sinuses or by maceration of organs in cases in which it cannot be procured easily from other locations.

Qualitative tests for carbon monoxide are very good. The changing of diluted normal blood to a brown or greenish brown does not occur after the addition of a small quantity of alkali, the original pink color being persistent. The spectroscope affords another test through the identification of carbon monoxide bands, but, contrary to some opinions, it is not highly sensitive.

In medicolegal work one should no longer be satisfied with qualitative tests. Quantitative estimations show-

ing the percentage of saturation in the blood, using preferably the methods of gas analysis devised by van Slyke, are essential for a proper interpretation of the case.

As to the amount of saturation necessary to produce symptoms it is usually stated in the literature, based chiefly on the work of Haldane and Henderson, that little inconvenience is felt until the blood is saturated about 20 per cent, that the saturation must reach 30 to 50 per cent to produce muscular weakness, incoordination and serious symptoms, and that it must be from 50 to 70 per cent to cause paralysis and death. If the saturation reaches 80 per cent it is rapidly fatal.

These figures unfortunately are based mainly on animal experimentation and Gettler<sup>4</sup> has never encountered in human beings a saturation higher than 65 per cent. It would seem improbable that a man could live long enough to show a saturation of 80 per cent.

In an analysis of approximately 2,000 human cases Gettler found that the saturation must reach from 18 to 20 per cent for symptoms to begin, a saturation of over 30 per cent is dangerous and most bodies found dead from carbon monoxide show a saturation of from 45 to 65 per cent. Deaths have occurred, however, with a saturation as low as 28 per cent.

These estimations of Gettler are being used constantly by the Medical Examiner's Office of New York City and Essex County as a basis for medicolegal testimony.

#### MODE OF ASPHYXIATION IN CARBON MONOXIDE POISONING

Death by inhalation of irrespirable gases is usually an asphyxiation, and one may, for instance, sign with accuracy a death certificate stating "Asphyxiation by illuminant gas, accidental, gas range, coffee pot boiled over."

Much, however, depends on the nature of the gas inhaled as to whether death is due to true asphyxiation, to some specific poisonous action of the gas, or to a combination of the two.

Henderson and Haggard<sup>5</sup> have called attention to two types of asphyxia that may be caused by the inhalation of noxious gases. In the first, which is caused by gases not usually considered as asphyxiants, for example, hydrocyanic acid gas, respiration is quickly stopped by their poisonous effects on the respiratory centers. The tissues are deprived of oxygen and the elimination of carbon dioxide ceases. In the second type, which is caused by the real asphyxiant gases, such as carbon monoxide, there is no cessation of breathing, except as a terminal event. The tissues are primarily deprived of oxygen but carbon dioxide continues to be eliminated and may be greatly depleted, as breathing with even more than normal vigor takes place. To the anoxemia is added a condition of acapnia.

It should be recalled that carbon monoxide is not truly a poisonous gas. Its fatal action is due chiefly to the replacement of oxygen. The gas itself is nonirritating and odorless.

Because the literature contains many vague references to thrombosis in carbon monoxide poisoning, recently there was called to my attention a medicolegal argument in which the so-called experts claimed that a gas asphyxiation from which the patient recovered was

responsible for the later development of an ordinary attack of coronary thrombosis

#### TREATMENT OF CARBON MONOXIDE ASPHYXIA

Henderson<sup>6</sup> has clearly shown that in asphyxiation by carbon monoxide the first stage is due to oxygen deficiency and the second stage to insufficient carbon dioxide caused by the rapid elimination of this gas. There is an associated compensatory decrease in the blood bicarbonates without great loss in the systemic alkali.

The treatment devised by Henderson and Haggard<sup>5</sup> has been so well established and has saved so many hundreds of lives that it must, for the present, be considered the method of choice. It is based on the restoration of an ample supply of oxygen and a normal amount of carbon dioxide, with a resultant normal relationship of oxygen, carbon dioxide and blood alkalis, causing the circulation, respiration, muscle tonus and mental status to return to normal.

On cessation of respiration, immediate artificial respiration by the prone pressure or other modern methods must be used. Such treatment as a mixture of oxygen and 7 per cent carbon dioxide administered by rescue squads, or up to and even higher than 10 per cent administered by qualified physicians, may be followed and continued after arrival at the hospital.

Blood transfusion, hypodermic medications, respiratory stimulants and intravenous injections are not necessary. A striking demonstration of the effectiveness of the treatment devised by Henderson and Haggard may be noted in the reduction of deaths from accidental asphyxiation in New York City during a period of five years, as shown in the table. This reduction is also due to such factors as the efforts of the Society for the Prevention of Asphyxial Deaths and better inspection of leaky fixtures by the department of health.

If respirations have been restored and carbon monoxide eliminated but the patient still remains unconscious, the treatment of the cerebral edema may be of some benefit.

The injections of methylene blue are not an antidote for carbon monoxide poisoning, since they cause the formation of methemoglobin and still further reduce the capacity of the red cells to absorb oxygen. Such injections are not only useless but may be distinctly harmful from their additional toxic effects.

#### SINGLE OR REPEATED EXPOSURE TO SMALL AMOUNTS OF CARBON MONOXIDE

The "Normal" Carbon Monoxide Content of the Blood—Gettler and Mattice<sup>7</sup> have recently investigated the carbon monoxide content of the blood in supposed normal individuals. They state that an ideal normal individual should have no carbon monoxide in his blood but that the average person under ordinary conditions is exposed so frequently that it is not possible to regard him as being carbon monoxide free unless procedures are employed that are suitable only for the detection of large amounts. They found that the hemoglobin saturation in twelve inmates of a state institution in an ideal rural locality was usually less than 1 per cent, while the blood of eighteen persons living in New York

City under conditions of minimal exposure ranged from 1 to 15 per cent. The saturation, however, in twelve street cleaners in New York City averaged about 3 per cent, and two taxicab drivers were found on several occasions to have a saturation of from 8 to 19 per cent. They also found that tobacco smoking appreciably increases the carbon monoxide in the blood and cannot be ignored in the interpretation of laboratory results.

*The Danger of Small Amounts to Motorists*—The evidence of the existing suspicion that some of the minor ailments such as weakness, dimming of vision, and nausea, especially common in people riding in improperly ventilated cars, may be caused by small amounts of carbon monoxide, had not been proved until recently.

The first complete study of gasoline propelled vehicles from the standpoint of combustion has recently been made in Connecticut by White,<sup>8</sup> an engineer. The investigation was later confirmed in Massachusetts.

Briefly, the survey consisted in determining (1) the efficiency of combustion of 250,000 automobile engines and (2) the gas analysis of the interior of numerous automobiles "flagged" on the road. Sixty per cent of cars in general operation contained measurable quantities of carbon monoxide and 7 per cent contained it in sufficient quantities to cause collapse of the driver with exposures of four or more hours.

The carbon monoxide usually enters the interior of the car from its own motor or from one preceding it on the road. The increase of carbon monoxide in the car may result from obvious causes, such as a poorly adjusted engine or an ill fitting exhaust pipe.

Although carbon monoxide is odorless, sharp exhaust odors attest that there is improper combustion and furnish a priori evidence of the presence of carbon monoxide.

It is highly possible that in some of the 85 per cent of all automobile accidents with undetermined causes the dulling of the reaction time, when quick coordinated movements are required, may be due to small amounts of carbon monoxide.

In a recent case of mine, a driver in a completely closed truck drove his vehicle into the back of a parked car for apparently no reason. The assumption was that he had fallen asleep. At autopsy, in addition to the obvious traumatic injuries, a pink lividity of the body and a cherry red color of the blood were noted. The latter was subsequently shown to have a 20 per cent carbon monoxide saturation.

#### THE SO-CALLED CHRONIC CARBON MONOXIDE POISONING

A condition similar to overtraining in athletes, noted in mechanics in automobile repair shops, workmen in gas plants and blast furnaces, and cooks working in small, badly ventilated kitchens, and characterized by such conditions as impairment of general health, nervousness and ill temper, has been attributed by Henderson<sup>1</sup> to exposure to small, more or less constant amounts of carbon monoxide. However, the frequent incidence of such minor ailments in other conditions, notably alcoholic conditions, loss of sleep and chronic diseases, will always make this a moot question, and unfortunately will open another opportunity for the compensation lawyers and physicians.

## ABSTRACT OF DISCUSSION

DR J N PATTERSON, Cincinnati I want to ask Dr Martland the method he used in determining the percentage of saturation of carbon monoxide in the blood, also what he thought of the accuracy of the pyrogallic-tannic acid outfit put out by the Bureau of Mines of Pittsburgh in determining the percentage of saturation of carbon monoxide in the blood

DR ALEXANDER O GETTLER, New York In the laboratory with which I am connected we use the van Slyke method for quantitative analysis When the amount of carbon monoxide is expected to be large, in bodies with pink coloration, we use the ordinary van Slyke method for measuring the volume of the liberated carbon monoxide For very small amounts of carbon monoxide we make use of van Slyke's manometric method

DR WILLIAM D McNALLY, Chicago When the body has been dead for thirty-six hours to a week, the blood is dark and the colors cannot be compared When the blood is old and dark, the carmine method or the dilution test cannot be used That statement is based on thousands of examinations of blood for carbon monoxide

DR HARRISON S MARTLAND Newark, N J All analyses are referred to the toxicologist A technic devised by Dr Gettler, based on the well known gas analysis of van Slyke, is being used

THE ADEQUACY OF TREATMENT IN  
THE CONTROL OF SYPHILIS

UDO J WILE, MD

Professor of Dermatology and Syphilology University of  
Michigan Medical School

ANN ARBOR, MICH

The public health aspects of an attack on disease focus on two problems first, the adequate treatment of existing cases so that they cease to be a menace to the individual infected or affected and to those about or in intimate contact with him, and, second, the prevention of the development of new cases The latter problem, far more important, is already an accomplishment in many infectious diseases Unfortunately, some of the most serious public health problems present insuperable difficulties in control Because of its unique natural history, the manner of its acquisition, the long duration of its potential dangers, and for many other reasons, the prevention of syphilis as a public health measure is perhaps the most difficult problem of all

To be sure, in time of national emergency, as during the late war, wonderful advances were made in the prevention of the spread of syphilis among the soldier population These were accomplished, however, under conditions not applicable to civil life and by means which could be applied only to large groups of men operating under military laws Further, while indirectly protecting the whole population, the laws were primarily concerned with the problem of keeping the male portion and only that part of military age free from infection

This paper will concern itself with another phase of syphilis control, namely, the adequacy of modern methods of treatment in preventing the late sequelae of the disease The full discussion of this problem quite naturally involves a taking of stock as it were, of the advances made in the armamentarium of treatment which have occurred within the past few years Have

these indeed advanced with the frontiers of knowledge concerning syphilis, biology, pathology and natural history? Is the profession better prepared today to treat syphilis than heretofore, and can it prevent those late sequelae which up to now are the evidence in part at least of the inadequacy of its previous efforts?

With regard to the first question, I believe it may be said that, although advances have occurred in methods of treatment, these are in no way comparable to those which have enhanced knowledge of the clinical, pathologic and biologic aspects of the disease The treatment of syphilis is still in a state of experimental flux Each year sees some new drug or modification of older methods advanced as the last word and each in turn is either rejected as useless or, after due trial, accepted as possibly adding something to accepted methods In the last two or three decades the arrival of arsphenamine has been heralded a cure at one dose of neoarsphenamine and silver arsphenamine, and adjoined improvements over the older drug, of bismuth, arsphenamine sulphonate and countless others, each falling far short of the anticipated promises, many rejected entirely, the remainder now carefully weighed as to what may be expected of them and added to the pre-existing armamentarium at the physician's disposal To these may now be added the definite advances achieved by the substitution of bismuth salts for those of mercury, and the application of fever therapy, artificially induced, in the treatment of neurosyphilis accidents

Among all the advances, one thing stands out as an axiom unchanged through centuries, that the basic ground, the understructure on which all treatment must be laid down, is the continuous use of a heavy metal With all the kaleidoscopic changes that have occurred in the management of syphilis, the continuous use of mercury and more latterly bismuth has been the most constant factor, and around this the modern syphilologist, until something better appears, must build his attack Looking back over the development of methods of treatment and changes in drugs used, it may safely be said that what is now set forth as adequate or as the best treatment today may well be discarded in the distant future, as have older methods in favor of those in use today The last word in the treatment of syphilis is still unspoken, and the ultimate solution and the successful search for a cure comparable to that which exists for certain other infections is, I believe, something to be attained in the very remote future

The answer to the second query, Are physicians better prepared by modern methods of treatment to prevent the late sequelae of the disease? may unhesitatingly be answered in the affirmative While practically any system of the body may be and frequently is attacked as a late sequel, those which are economically and physically the costliest are the accidents in the cardiovascular system, the late neurosyphilitic lesions and the multifarious manifestations which characterize the cases of heredo or congenital syphilis The most recent investigation and thought on these dreaded complications leads to the conviction that they are for the most part preventable accidents

During the past few years, a detailed study of clinical syphilis has been undertaken by five cooperative clinics under theegis of the United States Public Health Service The many thousand cases seen in these several clinics have been pooled and most valuable information concerning treatment, course, complications, prog-

Read before the General Scientific Meeting at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 12, 1934. Studies and Contributions from the Department of Dermatology and Syphilology, University of Michigan Medical School, service of Dr. Udo J. Wile.

nosis, effect on pregnancy, and many other phases of the disease have been gleaned and published. The results of these joint studies and a personal experience of over a quarter of a century convince me that the important factor in the causation of late accidents is inadequate treatment during the first year of the infection. Thus, the analysis of any group of late accidents, let us say of a thousand cases of cardiovascular syphilis or neurosyphilitic disease, would show a negligible percentage of these cases to have received an adequate treatment program. By adequate is not meant ideal treatment carried on over a period of two or three years, but a few months of energetic treatment with a combination of arsphenamine and heavy metal. A large number of the group indeed are represented by patients who have received no treatment whatever. Of these many again would be shown to have been misdiagnosed or unrecognized by the physicians, either passed off as soft sore (chancroid, herpes) or dismissed as nothing at all of consequence. This group thus left to infect others and to develop disabling late sequelae involving economic dependence, and in many cases premature death, are definitely preventable in the great majority, and their occurrence is an indictment against medical practice. It must be admitted, however, that a not inconsiderable number of patients with late accidents escape diagnosis and treatment not through the carelessness of the physicians but because of the unfortunate tendency of syphilis occasionally to occur early as an occult infection.

The chancre is not always an obvious phenomenon and not infrequently secondary manifestations occur in so evanescent a manner that they escape both the patient's and the physician's attention. This occult type of infection is particularly common in conjugal syphilis in women who contract their infection from a latently syphilitic husband.

The occurrence of late sequelae in this group could be prevented or cut down in numbers only if periodic health examinations, including a serologic test of the blood, were made at intervals and became a matter of general practice. Needless to say, such an examination would result in an enormous saving of life and in prolongation of economic usefulness, not only by the detection of occult syphilis but in the early diagnosis of many other organic diseases.

While the occult infected cases represent an appreciable proportion of the whole, one gains the distinct impression that the infection was either known and not treated or inadequately treated in the large majority of the cases of late sequelae.

The tremendous importance and influence of energetic adequate treatment as a preventive measure against late accidents is further borne out by the common experience of syphilologists who over a long period of time have been able to follow their adequately treated cases through years of good health and who can testify that but a very small number of such patients contribute to the group of late accidents. This has been my personal experience and I believe it is that of others having equal or longer periods of observation of such cases.

Mention has been made of adequate treatment, and it seems that this should be defined more accurately. Adequate treatment is that amount over a specified time which has served to protect the average patient from recurrence. In a sense it is empirical, but the cooperative studies have shown that a very fair degree

of protection is conferred by an amount of treatment very short of what may be considered ideal. Thus, from twenty to thirty injections of arsphenamine and perhaps double the number of injections of a bismuth compound have been shown to confer a very high rate of protection in a large group of early cases against recurrence and late accidents. This amount, however, should not be taken as axiomatic of all that may be required or approaching even the ideal. The weekly treatment over two or preferably three years with an insoluble bismuth preparation, prefaced by several courses during the first years or eighteen months of arsphenamine, is a safer course for the average physician to pursue. The damage to vital tissues does not begin late in the course of the infection. The trail is blazed in the septic period of the disease. It is in this stage that vital structures, the heart, the great vessels, the brain and the cord and all the viscera are invaded.

It is a peculiarity of *Spirochaeta pallida* to provoke a low grade of infection, which progresses very slowly, particularly in parenchymatous tissue and in blood vessels, thus producing a period of quiescence or latency that is equaled by no other disease and surpassed only by leprosy. It is for this reason that so many years elapse between invasion of an organ or tissue and its subsequent dysfunction from fibrous displacement or degeneration.

The energetic treatment in the invasive period, therefore, is the watchword or the best preventive measure against late tissue damage. During the early weeks and months, treatment must be vigorously and relentlessly carried out. If the early manifestations were resistant to treatment and not so easily masked by it, the prognosis would be vastly better. The ease and rapidity of the disappearance of early lesions is a factor tending to make light the seriousness of the infection to the patient and frequently undermines the vigor of the therapeutic attack on the part of the physician.

With regard to cerebrospinal late accidents, much valuable knowledge has come during the past two decades through the routine procedure of lumbar puncture during the early weeks of the infection. By this procedure it can be definitely established that cases of late cerebrospinal accident can be detected in their incipency by changes in the spinal fluid. Conversely, it can be determined that in the main, if a patient's spinal fluid remains negative during the first year, the integrity of his nervous system is preserved and he will not fall into the group having late neurosyphilitic accidents. The demonstration of early neurosyphilis, however, calls for energetic treatment not only to the constitutional infection but directly to the system involved. The institution of one form or another of intraspinal treatment in the early period, along with the constitutional treatment, has been shown definitely to protect the individual against a late neurosyphilitic accident. Too much emphasis cannot be placed on the necessity for early and repeated lumbar puncture during the first year of the infection, not only as a diagnostic measure but as an invaluable guide to the prognosis, as pointing to involvement or integrity of the most important of all systems.

Of tremendous importance and of real therapeutic merit has been the introduction of fever therapy into the therapy of late neurosyphilis. The contribution of Wagner von Jauregg of the induction of artificial malaria in the treatment of dementia paralytica has been the outstanding therapeutic procedure of recent times.

Not only has it been extremely successful in the treatment of selected cases of brain syphilis but it has led to a much earlier diagnosis and has been found to be extremely useful somewhat outside the field for which it was first suggested. Although the information concerning its use was given to the profession only a few years ago, the theory was not hastily conceived but was based on observations extending over a long time.

The extraordinary results occasionally achieved by malarial therapy have led to the conviction in many minds that much of what was formerly regarded as dementia paralytica possibly falls into some other groups of brain syphilis. It seems now fairly established that the syndrome of dementia paralytica involving confusion of ideas and disorientation, together with the characteristic spinal fluid changes, can really be induced by syphilitic encephalitis and occasionally even by cases of cerebral edema associated with syphilitic leptomenigitis. Cases of the latter may present forms of psychosis involving character changes and behavioristic phenomena that closely simulate those due to actual degeneration encountered in late dementia paralytica. The very prompt recovery of some of these patients under malarial therapy can mean only that one is dealing with a much more acute process than occurs in dementia paralytica. I believe that out of these cases will come a clearer concept and differentiation between true dementia paralytica and cases of syphilitic psychosis with active cortical lesions.

However, it seems now evident from the cases treated with malaria that even in advanced dementia paralytica much of the confusion, disorientation and other maladjustments that make up the syndrome may not be due to permanent damage in the form of degeneration. In part, at least, they must be due in those cases which show recovery or partial recovery to acute inflammatory or edematous processes which are absorbed or disbursed as a result of the malarial treatment.

As so frequently happens with a new remedy, the malarial treatment has been found of equal usefulness in other forms of neurosyphilis. My own experience leads me to regard it as of equal value in the treatment of selected cases of tabes, notably those with intractable foot pains and various forms of visceral crises which are so resistant to other forms of treatment. In these types of cases, as well as in diffuse types of cerebrospinal syphilis, it has been possible in selected cases to achieve most happy therapeutic results.

The literature during the past few years is replete with other forms of fever-inducing agents which, it is hoped, are improvements on the induction of artificial malaria. Time does not permit me to go into detail into the results of the treatment of neurosyphilis, both late and early, with fever induced by other agents, both physical and biologic. From the increasing reports, it would seem that fever itself induced from any source, either in paroxysms or continuously, is of some value in the treatment of neurosyphilis. I am still unconvinced, however, that the various newer forms of fever induction have thus far demonstrated any great advantage over the use of malaria, and I am satisfied from my own experience that the fever induced by ordinary bacteria or their products in no way compares with the results achieved by malarial inoculation.

Perhaps a word of caution might here be injected regarding the risks of fever therapy. There are certain definite contraindications to its use, particularly advanced age, cardiac lesions and other organic dis-

ease. Even under the most careful selection, the treatment occasionally not only fails but under certain circumstances may be attended by a fatal outcome.

During the last few decades there has been a great advance in the methods and results of treatment in that large group of innocent victims of syphilitic disease who acquire their infection in utero. Much valuable information has been gained concerning the treatment of the expectant syphilitic mother, and it can definitely be stated that, in the majority of cases in which the treatment is begun during the early months of pregnancy, not only are the chances of a living child enormously enhanced but the many developmental structural defects as well as the active syphilomas that characterize the syphilized child can be definitely prevented. The intelligent treatment of a syphilitic mother and the effect of this treatment on the unborn child, as carried out along modern lines, represents a most gratifying stride toward therapeutic effectiveness. It is safe to predict that, if physicians at large applied to the treatment of syphilitic expectant mothers the principles laid down as a result of the studies of the cooperative group, the vast numbers of syphilitic children seeking relief from the unfortunate sequelae of their inherited infection would be enormously decreased, as would also the fetal mortality from intra-uterine infection.

Considerable progress has been achieved also in the successful treatment of children not treated during intra-uterine life but developing the stigmas and manifestations of intra-uterine infection and presenting themselves with the many-sided pictures, both developmental and active, of congenital syphilis.

Modern studies teach that even the worst case of interstitial keratitis, the most common and the costliest form of congenital syphilis, can be successfully treated and children restored to useful and independent life through the prolonged and energetic treatment of their condition. It is in these forms of congenital syphilis that a drum fire of attack must be directed against the infection. Not only are the arsphenamines and bismuth compounds necessary over a long period of time, but it is in these cases particularly that the iodides in combination with the others are of greatest use. Coupled with this form of treatment, there is special ophthalmologic treatment involving continuous miastriasis.

The unfortunate cases of blindness due to interstitial keratitis are for the most part preventable occurrences. Through long continuous treatment, at times attended by repeated recurrences, these conditions can be successfully treated and for the most part with a workable amount of visual restoration. Looking back over thousands of cases treated, I count as one of the happiest therapeutic results those cases in which syphilitic women through energetic treatment have given birth to healthy infants, and the hundreds of malformed and partially or totally blinded children, for the most part mentally normal, who have been restored to a useful and normal life through the prolonged use of modern methods of treatment.

As stated before, the treatment of syphilis is still in a state of constant flux. The happy results achieved during the last three decades as a result of the pooled experience of observers in different parts of the country, and as a result of newer methods involving not only new drugs and new procedures but also greater refinement in early diagnosis, lead to the conviction that the next few decades will see, if not the last word, at

least equally great progress in the treatment of already infected patients

The prevention of syphilis from the public health standpoint is a major problem deserving of the greatest effort on the part of the agencies concerned with the prevention of diseases

University Hospital

## INTESTINAL PARASITIC WORMS IN THE UNITED STATES

### THEIR DIAGNOSIS AND TREATMENT

HAROLD W BROWN MD

NASHVILLE, TENN

The search for drugs for the expulsion of the large worms of man is very old. Old accounts list many drugs and heroic treatments devised to expel *Ascaris* and tapeworm. Since the hookworm epidemic among workers building the famous St Gothard tunnel some fifty years ago, many drugs for the treatment of hookworm disease have been introduced. The discovery by C W Stiles of the wide prevalence and pathologic significance of hookworm disease in this country and the organization by the Rockefeller Foundation of treatment campaigns against this disease led to the treatment of millions of cases. Likewise, large numbers of persons harboring *Ascaris*, whipworm, tapeworm and pinworm have been treated with various drugs. There are, therefore, certain groups who have had considerable experience in the treatment of these parasitic infestations. Much has been written about the drugs used in the treatment of these various infestations, but most of the articles are written for those specializing in the treatment of parasitic diseases and lack certain basic information that is necessary for those less acquainted with the various factors involved. For this reason, I have brought together in as concise a form as possible data which should be of help to the general practitioner in the treatment of individual cases of infestation by any of the common intestinal helminths found in the United States.

The ridding of a patient of intestinal parasites has for centuries been considered a serious procedure, and violent methods have been used to that end. One reads of long periods of pretreatment starvation and purgation, followed by the administration of the drug and then by another period of terrific purgation. Much of this treatment was felt necessary owing to the inefficiency of many anthelmintics, and it is not surprising that the treatment of intestinal parasites was carried out with a good deal of dread because of the danger of such procedures. All the older and more commonly used anthelmintics are occasionally quite toxic, and it is well known that each causes severe intoxication in certain individuals, this usually being ascribed to the idiosyncrasies of the patient. Although thousands of cases have been treated with some of these substances without a fatality or definite signs of intoxication, severe injury and even death have followed without any warning the administration of these anthelmintics in proper therapeutic amounts to apparently normal individuals.

During the past ten years there have been found for the treatment of certain types of intestinal helminths

several new substances which are fully as effective as any of the older remedies and which, as far as is known at present, can be given without fear of intoxication. On the other hand, there are no effective and safe drugs for all types of intestinal helminths. I shall outline the various treatments that have been found most effective and point out the dangers inherent in such forms of treatment.

For successful treatment of patients harboring helminths one must consider the life cycle of the parasite, the method for determining its presence, the substances that may be used most successfully against a particular parasite and the details of their administration, as well as methods of estimating the effectiveness of treatment. It should be remembered that these various species of parasites of such extremely different types must be considered and treated individually, for a drug that will remove practically 100 per cent of one type of parasite may be ineffective against another.

### DIAGNOSIS OF THE PRESENCE OF INTESTINAL HELMINTHS

Since all the common intestinal helminths to be described, with the exception of *Trichinella*, can be diagnosed by examination of the stool for the worms or their eggs, it is inexcusable to treat a person for worms unless a positive diagnosis has been made. Diagnosis of worms from symptoms alone is likely to be very inaccurate, and it is not at all scientific after such a haphazard diagnosis to subject a patient to treatment that may be very disagreeable.

The common intestinal helminths found in this country which I shall consider are the hookworm, *Necator americanus*, the roundworm, *Ascaris lumbricoides*, the whipworm, *Trichuris trichiura*, the pinworm or seatworm, *Enterobius vermicularis*, *Strongyloides stercoralis*, *Trichinella spiralis*, the beef and pork tapeworms, *Taenia saginata* and *Taenia solium*, the fish tapeworm, *Diphyllobothrium latum*, and the dwarf tapeworm, *Hymenolepis nana*.

The presence of these worms can be determined by (a) eggs in the stool, hookworm, *Ascaris*, *Trichuris*, *Diphyllobothrium*, and *Hymenolepis*, (b) eggs or segments in the stool, *Taenia saginata* and *T. solium*, (c) worms in the stool or about the anus of the patient at night, occasionally eggs in the stool, *Enterobius*, (d) larvae in the stool, *Strongyloides*, and (e) adult worms in the stool during the first week of infestation, or larvae in excised muscle and spinal fluid after the first week, *Trichinella*. Marked eosinophilia, diarrhea, muscle cramps and edema of the lids are important diagnostic aids.

The simplest method of finding eggs is to examine a fecal smear on a glass slide. In preparing a smear, a small bit of the feces to be examined should be mixed with water on an ordinary glass microscopic slide. The smear should be mixed with enough water so that ordinary print can be seen through it. If the smears are too dense, it will greatly lessen the chance of finding the eggs. The accuracy of the smear method depends on the number of slides examined. A single smear will disclose heavy infestations, but to detect lighter cases a number of slides must be examined. If no eggs are found by the smear method, it is well to stir up in a small container a gram of feces in 20 cc of saturated salt solution and allow it to stand for from fifteen to twenty minutes. The eggs will float up to the surface and can be transferred to a slide by touching the mouth

of an inverted test tube to the surface of the fecal flotation mixture. Unfortunately, operculate or porous eggs do not float in a salt solution, so this method is not satisfactory for the detection of *Diphyllobothrium* or *Taenia*. Since ascarids pass an enormous number of eggs, several negative smears indicate that no ascarids are present. One should, however, remember that in very rare cases one or more male ascarids may be present but overlooked, owing to the absence of eggs. Since hookworms, *Hymenolepis*, *Diphyllobothrium* and *Trichuris* pass fewer eggs than *Ascaris*, a more careful examination is necessary to prove the presence of these parasites. However, if several smears and the flotation examination are carefully carried out and no eggs are found, it may be assumed that the patient has no worms or that there are probably not a sufficient number present to be of pathologic significance. Those interested in diagnosing very lightly infested persons should refer to the method of Lane. His method, though very accurate, involves the use of apparatus too expensive for the average physician who has only an occasional case to diagnose.

The two *tenias* and the pinworm do not pass their eggs regularly and, because of this, several whole stools passed over a period of several days should be examined both macroscopically for tapeworm segments or adult pinworms and microscopically for eggs of both worms before one feels certain that none of these parasites are present. In case of negative stools a magnesium sulphate purge may often be of help in causing the passage of tapeworm segments or adult pinworms. In cases in which tapeworms and pinworms are suspected, it is well to instruct the patients to inspect their stools for segments or wormlike material, which should be brought to the physician. If the suspected material is unrecognizable, it can be macerated with water and examined microscopically for any contained eggs. Inspection of the perianal region an hour after the patient has retired will sometimes reveal adult pinworms, and perianal scrapings examined microscopically will often disclose pinworm eggs.

Many states have laboratories where fecal diagnosis is a part of the routine and where specimens may be sent for examination. The accompanying illustration of the different types of eggs is given for those unfamiliar with them.

#### PURGATION IN ANTHELMINTIC TREATMENT

Adequate purgation following most anthelmintics is of great importance and may aid in several ways. Macht and Finesilver<sup>1</sup> have shown that the absorption of many drugs is decreased by the administration of sodium sulphate solutions. Likewise, the purge may hasten the elimination of the unabsorbed anthelmintic or aid in its distribution along the intestinal tract, preventing local injury and allowing it to come in contact with worms far down in the intestine. The purgative should be given as early as is consistent with the efficacy of the anthelmintic, or sooner if safety requires it.

Purges should be given in large enough quantities to produce results, and it is inadvisable to give them in small or divided doses. In case the first purge does not act within three to four hours and the patient shows signs or symptoms of toxicity from the anthelmintic, purgation should be repeated and aided by enemas. One

must use judgment in this matter, however, for patients have been exhausted and their lives endangered by terrific purgation following anthelmintic administration. After the use of certain drugs, intestinal obstructions caused by *Ascaris* have been found at operation or autopsy, and no purge should be given to patients suspected of having intestinal obstruction. Violent purgation during pregnancy is contraindicated. The patient should not eat until the purge has acted. In persons whose bowels are constipated the intestinal tract should be opened up with a purge and enema the day before anthelmintic administration. A dose of 30 Gm (1 ounce) of magnesium sulphate is satisfactory for an adult. Children's doses can be calculated on a basis of 2 Gm of magnesium sulphate for 10 pounds (4.5 Kg) of weight, which is approximately a teaspoonful for each 20 pounds of weight. The salts should be dissolved in a glass of water, and I have found that children complain less when it is followed by a small amount of sweetened water to take the taste out of the mouth.

Some advocate the substitution of sodium sulphate for magnesium sulphate on the basis that sodium is less toxic than magnesium. Theoretically, this may be of importance in treatment with carbon tetrachloride wherein the calcium balance is important, as it is known that magnesium is antagonistic to calcium. Practically, however, many persons object to the disagreeable taste of sodium sulphate and it is difficult to persuade children to take a full dose of it.

#### HOOKWORM, *NECATOR AMERICANUS*

The adult hookworms are found throughout the small intestine, and the females pass from 5,000 to 10,000 eggs daily. These eggs passed out with the stool develop rapidly in moist, warm soil and in several days contain active larvae which force their way out of the egg shells and, after undergoing further development over a period of about a week, are capable of infecting man. Infection occurs when the bare feet or hands come in contact with the infective larvae, which penetrate the skin, effect an entrance into lymphatics or veins, and are carried to the right side of the heart. The larvae on being carried to the lungs rupture the capillaries and force their way into the alveoli. They migrate by way of the bronchi up the trachea to the pharynx, are swallowed and pass to the small intestine, where they attach themselves and grow to maturity. Adult worms are about one-half inch in length. The period necessary for the development of these parasites to the egg-laying age after infection is approximately six weeks. It has been shown that the hookworm obtains nourishment by sucking the blood of its host, and it is believed that hookworms live as long as several years.

Thymol, betanaphthol, oil of chenopodium, carbon tetrachloride and tetrachloro-ethylene have been given to hundreds of thousands of patients. Thymol in therapeutic doses often produces unpleasant symptoms, such as extreme dizziness and vomiting. Oil of chenopodium is a definitely toxic substance when given in an overdose. Given in the accepted therapeutic dose, it may cause many symptoms ranging from giddiness and dizziness to severe collapse and, in certain cases, its administration has been followed by death. Betanaphthol has been used less extensively on account of its well known toxicity. Carbon tetrachloride is very effective but may produce severe central necrosis of the liver, even in moderate doses. In spite of this, millions

<sup>1</sup> Macht, D. I. and Finesilver, E. M. The Effect of Saline Purgatives on the Absorption of Other Drugs. *Bull. Johns Hopkins Hosp.* 33: 330 (Sept.) 1922.

of persons treated with this substance have had no serious signs or symptoms, but occasional deaths are reported following its use, especially in debilitated or alcoholic persons. There seems to be no reason for using carbon tetrachloride in the treatment of hookworm disease, as tetrachloro-ethylene, which was introduced by Hall and Shillinger<sup>2</sup> and which belongs to the same series of halogenated hydrocarbons, is fully as effective and apparently nontoxic. Tetrachloro-ethylene has been given to enormous numbers of patients without any signs of intoxication. Lambert<sup>3</sup> recently reported the successful treatment in 46,000 cases, using from 28 to 40 cc of tetrachloro-ethylene in adults. In therapeutic doses, it produces no liver damage and, therefore, differs from carbon tetrachloride. The intoxications following carbon tetrachloride are secondary to guanidinemia following liver damage. Crystalline hexylresorcinol has recently been introduced into medicine as an anthelmintic, and, although it is less effective than tetrachloro-ethylene against hookworm, it has the advantage, as will be pointed out later, of removing also a high percentage of *Ascaris*. This drug will be discussed under ascariasis.

#### TREATMENT OF HOOKWORM DISEASE WITH TETRACHLORO-ETHYLENE

(a) *Preparation of the Patient*—No preliminary measures need be taken before treatment. If one wishes, one may give a light evening meal followed later in the evening by a saline purge, in the hope that the intestinal tract will be emptied and thus allow the drug to come in closer contact with the worms.

(b) *Administration of Tetrachloro-Ethylene*—Treatment should be carried out in the morning, and breakfast must be omitted. The usual adult dose of tetrachloro-ethylene is 3 cc, although some workers have given 4 cc to large numbers of persons.<sup>4</sup> Children may be given 0.2 cc for each year of age up to 15 years. The drug should be given in a single dose in either of the following ways:

1. A purgative of magnesium sulphate should be dissolved in half a glass of water and the liquid tetrachloro-ethylene added to this and the whole shaken up and swallowed at one time. Any of the drug adhering to the glass should be rinsed off with additional water and taken.

2. Tetrachloro-ethylene may be given in hard gelatin capsules followed at once by the magnesium sulphate purge. The patient should rest and wait until the purge acts before eating. In some cases a second purge may be necessary to produce a bowel movement.

(c) *Signs and Symptoms*—Pharmacologic studies<sup>5</sup> have failed to show any changes following reasonable doses of tetrachloro-ethylene that would indicate a toxic action. This substance, like chloroform, belongs to the group of anesthetics, and it is possible to anesthetize an animal completely by the inhalation of tetrachloro-ethylene vapor. It is obvious that in certain individuals absorption of tetrachloro-ethylene may take place and cause slight dizziness and feelings of giddiness such as one might feel after the absorption of any anesthetic.

This, however, should not be taken as an indication of intoxication, and the patient may be told that such slight disturbances may be expected.

(d) *Contraindications*—Although tetrachloro-ethylene is apparently nontoxic even after absorption, as shown by the absence of pathologic changes in dogs following its inhalation for several hours, it is well to avoid absorption and therefore best to refrain from taking fats or alcohol just before or just after treatment, as both of these substances are known to cause an increased absorption of similar compounds.

(e) *Efficiency*—A stool examination should be made about two weeks after treatment. This delay allows

Eggs and larvae of important American human helminths (Original by Mrs. J. T. Lipe). 1 *Taenia saginata* (*Taenia solium* is very similar) 2 *Trichuris trichiura* 3 *Diphyllobothrium latum* 4 *Hymenolepis nana* 5 *Ascaris lumbricoides* (unfertilized) 6 *A. lumbricoides* (fertilized) 7 *Strongyloides stercoralis* 8 *Necator americanus* 9 *Enterobius vermicularis*

time for any worms that may not be killed, but have had their egg-laying temporarily inhibited, to regain this function. If no eggs can be found in several carefully examined fecal smears or in a flotation preparation, the patient is, for all practical purposes, cured. Various workers report from 77 to 97 per cent of hookworms removed by a single treatment of tetrachloro-ethylene.<sup>6</sup>

Tetrachlorethylene in the Treatment of Hookworm Disease. *Am. J. Trop. Med.* 6: 451 (Nov.) 1926.

TREATMENT OF HOOKWORM DISEASE WITH  
HEXYLRESORCINOL

Tetrachloro-ethylene is more effective than hexylresorcinol in the removal of hookworms and for mass treatment is the drug of choice. It does, however, produce a marked feeling of giddiness in many. For this reason, I feel that in the treatment of individual cases, especially children and debilitated and pregnant persons, hexylresorcinol is very useful. In therapeutic doses it usually produces no unpleasant symptoms, and those treated may go about their usual occupations. The purge is usually given twenty-four hours after the hexylresorcinol but may be entirely omitted without impairing the efficiency or safety of the treatment. If desired, a laxative such as phenolphthalein may be substituted for the more violent purge. Although one treatment will remove approximately 70 per cent of the hookworms, a number of patients will be cured by a single treatment, and, as hexylresorcinol is not unpleasant to take, it can be repeated several times until the patient is cured. The method of administration is described under hexylresorcinol treatment of ascariasis.

TREATMENT OF HOOKWORM DISEASE WHEN  
ASCARIS ALSO IS PRESENT

It has been shown that treatment with carbon tetrachloride of hookworm patients who also harbor *Ascaris* is sometimes complicated by the fact that the ascarids are vomited, passed through the nose or migrate in such large numbers that they block the respiratory passage and, in other instances, form masses of worms that cause intestinal obstructions. Since it is possible that tetrachloro-ethylene may act similarly, it is advisable to remove *Ascaris* before treating with tetrachloro-ethylene.

For the treatment of patients harboring both *Ascaris* and hookworm, hexylresorcinol is particularly effective, as it will remove practically all the ascarids and about 70 per cent of the hookworms with a single treatment. This drug has the further advantage that it kills the ascarids and prevents their migrating or forming in masses and producing intestinal obstruction. Although a single treatment with hexylresorcinol is not as effective against hookworm as one dose of tetrachloro-ethylene, it can be repeated, and two treatments will remove from 85 to 90 per cent of the hookworms and usually all the ascarids. None of the patients who have had repeated treatments with hexylresorcinol complained of any unpleasant symptoms, and I have no reason to believe that such treatments are dangerous. The method of treatment with hexylresorcinol is described in the section on the treatment of ascariasis with hexylresorcinol.

Some workers recommend the use of a mixture of oil of chenopodium with tetrachloro-ethylene, which will remove *Ascaris* and hookworm simultaneously. The usual procedure,<sup>7</sup> if oil of chenopodium is to be used with tetrachloro-ethylene in mixed infestations of hookworm and *Ascaris*, is to give in one dose a mixture of 0.05 cc of chenopodium for each year of age up to 20 years and 0.1 cc of tetrachloro-ethylene for each year of age, an adult dose being 1 cc of oil of chenopodium plus 2 cc of tetrachloro-ethylene. This should be followed in an hour by a magnesium sulphate purge and nothing should be eaten until the patient's bowels are moved. The combined oil of chenopodium and tetra-

chloro-ethylene treatment<sup>8</sup> will remove as high as 98 per cent of the hookworms and approximately 65 per cent of the ascarids. It should be remembered, however, that oil of chenopodium, owing possibly to idiosyncrasies of some patients, is at times very toxic.

LARGE ROUNDWORM, *ASCARIS LUMBRICOIDES*

The female *Ascaris lumbricoides* passes approximately 200,000 eggs a day. These eggs develop in the soil and become infective after a period of two weeks or more. The eggs are swallowed and pass to the small intestine, where the larvae emerge from the shells, penetrate into the lymphatics or venules of the intestinal wall and are carried by the blood stream to the right side of the heart and from there to the lungs, where they migrate out of the capillaries into the alveolar spaces, crawl into the bronchi, and then pass up the trachea into the esophagus and are again swallowed and carried to the small intestine, where they develop in six weeks into adult worms. Adult worms vary from 8 to 14 inches in length. They are not blood suckers but feed on the intestinal contents and probably live from six months to a year. Ascarids are not always harmless parasites and they are a source of danger because of their wandering habits. Many cases have been reported of their presence in the bile ducts, liver, pancreatic duct and pancreas. Likewise, they have been found in masses causing intestinal obstruction and have even caused a fatal peritonitis by piercing the intestinal wall.

Numerous substances have been used for the treatment of ascariasis. Santonin has been used for centuries and is moderately effective in safe doses, but it is somewhat expensive. Oil of chenopodium has been extensively used for the past twenty years and is very effective against both *Ascaris* and hookworm. It has been used in literally millions of cases,<sup>9</sup> but a number of deaths have been reported following its use, and it is considered a dangerous drug, as one never knows when death may occur from its use. The active and toxic principle of oil of chenopodium is called ascaridole, and, unfortunately, various samples of oil may vary as much as 75 per cent in ascaridole content. Because of this, one is never sure how much ascaridole a dose of oil of chenopodium contains, and collapse and death have followed therapeutic doses of this substance.

Because of the lack of a safe and effective ascaricide, my associates and I have spent several years in attempting to find a drug that could be used with less danger. In 1930,<sup>10</sup> such a drug was found in hexylresorcinol. This drug is not effective against *Ascaris* in the forms in which it is put on the market, namely, as Caprokol, an olive oil solution of the drug, or as Hexylresorcinol S T 37, a glycerin preparation. In such solutions the hexylresorcinol remains in solution and does not attack the parasite. However, it has been given in the form of pills of crystalline hexylresorcinol in several thousand cases and found to be very effective, a single dose removing between 90 and 100 per cent of *Ascaris*. It is an apparently harmless substance to take in this manner. It has been given in more than 200,000 cases in the form of the oil solution as a urinary antiseptic for

<sup>8</sup> Kendrick, Schapiro and Stoll.

days and even months in doses much larger than the single administrations that we have suggested for the treatment of parasitic infestations. Thus far, no deaths or serious intoxications have been reported from the use of hexylresorcinol. There is, however, one serious drawback to its general use. If the pills are chewed up, they cause severe local irritation of the mucous membranes of the mouth with loss of taste and discoloration of the lips and face if the saliva containing the drug comes in contact with these tissues. This irritation is, however, entirely superficial and the patient recovers from it within a few days, but its occurrence caused so much criticism of the manufacturers when they put this substance on the market for general use that it has been withheld until some method of administration can be devised that will make it impossible for patients or physicians who do not follow instructions as to its use to obtain such annoying results.

#### TREATMENT OF ASCARIASIS WITH HEXYLRESORCINOL

(a) *Preparation of the Patient*—The one precaution that must be taken with hexylresorcinol is to be certain that the intestinal tract is empty when the drug is given, as hexylresorcinol will combine with food and have little action on the parasite. For this reason it is advisable for the patient to eat only a light supper on the evening before treatment. If the patient also harbors hookworm, a magnesium sulphate purge may be taken after the evening meal.

(b) *Administration of Hexylresorcinol*—The following morning, breakfast should be omitted and the patient treated early. The dose of hexylresorcinol is 0.1 Gm for each year of age up to 10 years, the adult dose of 1 Gm being given to those over 10 years of age. Hexylresorcinol should be given in the form of pills and swallowed with a little water. If children are treated, it is essential to see that the pills are actually swallowed and that none remain in the mouth to be chewed later. If the child is unable to swallow the pills, they can be easily pushed down the throat by any competent physician. In no case should the pills be entrusted to parents who may administer them carelessly, for if the pills are chewed up they will be certain to cause a superficial, annoying burn. The patient may be allowed to drink as much water as he pleases and go about his daily routine as long as he refrains from eating for five hours after treatment. A magnesium sulphate purge is given on the following morning to hasten the expulsion of the dead worms.

(c) *Signs and Symptoms of Toxicity*—In most cases there is no discomfort whatever after taking this drug, patients going about their usual daily routine and children carrying on their work at school without any complaint. A few patients may complain of slight abdominal discomfort or nausea and very rarely a patient may vomit, but these cases are often associated with the patient's having eaten against advice after the administration of hexylresorcinol. A few notice a marked cathartic action after taking the drug.

(d) *Contraindications*—Except for the local irritation, I know of no contraindications to the use of hexylresorcinol. Alcohol has been taken after the administration of this substance without apparently causing increased irritation, but I would suggest that alcohol be avoided during the period of treatment.

(e) *Efficiency*—The ascarids are not all passed immediately after treatment but may appear in the

stool over a period as long as ten days. Therefore the post-treatment stool examination should be delayed for two weeks from the date of treatment. If eggs are still present, a second treatment can be given. In our large series of cases studied by the Stoll egg-counting method, from 90 to 100 per cent of all the ascarids were removed with a single treatment and approximately 70 or 80 per cent of these patients became completely free from these parasites.<sup>11</sup> After two such treatments, from 93 to 98 per cent were completely cured.<sup>12</sup> Hexylresorcinol also removed approximately 70 per cent of the hookworms and 30 per cent of the whipworms.

#### TREATMENT OF ASCARIASIS WITH OIL OF CHENOPODIUM

(a) *Preparation of the Patient*—The patient eats a light evening meal and, if the bowels are constipated, a saline purge is given on the evening before treatment, and a soapsuds enema just before treatment in the morning is advised. The patient should remain in bed during the treatment.

(b) *Administration of Oil of Chenopodium*—Although 3 cc of this oil has been given to hundreds of thousands of patients, it is agreed by those who have had the most experience with this drug that the total adult dose of 15 cc is the maximum that should be given.<sup>13</sup> The doses for children are shown in the accompanying table.

As an overdose of the oil of chenopodium may be toxic and as different samples of oil of chenopodium vary greatly in viscosity, the dose should always be measured and never given by drops. (Different droppers deliver from 18 to 70 drops per cubic centimeter of this substance.) Considerably larger doses of the oil than those just shown have been given in a large number of cases,<sup>14</sup> but both the number of intoxications and their severity increase with increase in the size of the dose. The oil of chenopodium should be given in hard, gelatin capsules, divided into two equal doses, administered two hours apart. One hour after the second dose of chenopodium a magnesium sulphate purge should be administered. Small children who cannot swallow a capsule may be given the drug on sugar. The patient should be kept under observation during treatment and if symptoms arise after the first dose the second dose of oil of chenopodium should be omitted and the purge given at once. No food is allowed until after the bowels have moved. As children are especially susceptible to toxicity from oil of chenopodium, many workers prefer to mix the chenopodium with castor oil, which apparently decreases its toxicity and also its efficacy against *Ascaris*. The total dose of oil of chenopodium should be dissolved in castor oil and given as a single dose. From 1 to 2 cc of castor oil for each year of age is adequate for this treatment. A magnesium sulphate

Treatment of Hookworm Infection. *J A M A* 70: 499 (Feb 23) 1918. Smilie W G and Pessoa S B. A Study of the Anthelmintic Properties of the Constituents of the Oil of Chenopodium. *J Pharmacol & Exper Therap* 24: 359 (Dec) 1924.

14 Molloy<sup>11</sup>, Heiser<sup>15</sup>, Caus J F and Mhaskar K S. The Correlation Between the Chemical Composition of Anthelmintics and Their Therapeutic Values in Connection with the Hookworm Inquiry in the Madras Presidency. II. Oleum Chenopodii. *Indian J M Research* 7: 570 (Jan) 1920.

purge should be given if the castor oil purge does not act within several hours. It is felt by some who have had considerable experience in the administration of the oil of chenopodium that free purgation following treatment is of the utmost importance in order to avoid absorption of the drug and toxic manifestations.

(c) *Signs and Symptoms of Toxicity*—A great many disturbances, even deaths, have been reported after the use of oil of chenopodium. The most striking phenomenon is general collapse, which may occur several hours after treatment. Other cases will show vomiting, dizziness, tingling of the hands and feet and muscular incoordination. Severe deafness, even permanent deafness, has followed the use of oil of chenopodium. A liberal diet of carbohydrates for several days previous to treatment is said to reduce the frequency of toxic symptoms.

(d) *Contraindications*—The use of oil of chenopodium is contraindicated in very young children, persons suffering from renal disorders or severe malnutrition, and during pregnancy. In gastro-intestinal disorders it should also be given with caution. Persons suffering from chronic constipation should have the bowels opened by a saline purge and soapsuds enema before treatment with oil of chenopodium.

(e) *Efficiency*—Different workers who have treated moderately large series of cases with oil of chenopo-

mercurous chloride are on the market. For children a dose of one-sixth grain (0.01 Gm.) for each year of age is well tolerated. For adults from 3 to 5 grains (0.2 to 0.3 Gm.) may be given.<sup>16</sup> Early the following morning (between 6 and 7 a. m.) a magnesium sulphate purge should be given. Treatment should not be repeated unless *Ascaris* eggs are found in the stool two weeks later.

Hall<sup>17</sup> and others believe that santonin increases its efficacy against *Ascaris* when given in small doses over a number of days. The usual adult dose is from 1 to 2 grains (0.06 to 0.12 Gm.) and for children from one-fourth to one-half grain (0.015 to 0.03 Gm.), depending on the age and size. This dose should be given several hours after breakfast for seven consecutive days. An equal amount of mild mercurous chloride should be added and no other purgative given. If eggs are still present in the stool two weeks after the completion of this treatment, the series of treatments may be repeated.

(c) *Signs and Symptoms of Toxicity*—Symptoms of poisoning vary from slight anomalies of perception, vomiting, abdominal pain, diarrhea and hematuria to convulsions, coma and death. The marked toxicity is usually due to large doses or long continued dosing. Some workers believe that a dose of 3 grains (0.2 Gm.) should not be exceeded, while others have used doses in large series with 5 grains (0.3 Gm.) without any untoward results.

(d) *Contraindications*—It is not advisable to give santonin on an empty stomach or in an oily cathartic, as these conditions favor absorption.

(e) *Efficiency*—The single dose method of treatment has been found highly effective, an average of 90 per cent of the ascarids being removed and from 60 to 80 per cent of the cases being cured by a single dose.<sup>18</sup> Pinworms also are removed by santonin.

#### WHIPWORM (TRICHURIS TRICHIURA)

The life cycle of *Trichuris* is relatively simple. The eggs pass out with the stools and develop in moist soil to the infective embryo stage in several weeks. On being swallowed by man, the larvae escape from their shells and are carried down the intestine to their habitat in the cecum. They attain adult size, from 1½ to 2 inches, in about one month. It is probable that they suck blood. *Trichuris* sews its long, slender, anterior end into the intestinal mucosa, and this habit combined with its position far down in the intestinal tract makes expulsion by drugs difficult.

#### TREATMENT OF TRICHURIASIS

Several of the common anthelmintics will remove a small percentage of whipworms. Thus tetrachloroethylene<sup>19</sup> and oil of chenopodium<sup>19</sup> each will remove about 20 per cent of these worms, and hexylresorcinol, when given as recommended for *Ascaris*, will remove from 30 to 50 per cent.<sup>20</sup> It appears at present that repeated treatments with hexylresorcinol offer the best chance of removing this parasite.

Leche de higueron, the latex of *Ficus laurifolia*, is used extensively in South America against whipworm.

*Dosage of Oil of Chenopodium for Children*

Age Years	Dose, Gm.	Age Years	Dose, Gm.
4	0.2	13-14	0.8
5-6	0.3	15-16	1.0
7-8	0.4	17-18	1.2
9-10	0.6	19-20	1.5
11-12	0.7		

dium report that from 70 to 99 per cent of *Ascaris* is removed by a single treatment and from 35 to 96 per cent of the cases will be found negative.<sup>15</sup> If *Ascaris* eggs are found in the stools two weeks after treatment, a second treatment may be given, but to avoid cumulative effects in no case should chenopodium be given before the lapse of at least two weeks. Approximately 60 to 70 per cent of the hookworms harbored are removed by a single treatment. Likewise, numbers of *Trichuris*, *Enterobius* and *Hymenolepis* are removed by this drug.

#### THE TREATMENT OF ASCARIASIS WITH SANTONIN

Santonin has been a favorite remedy against roundworms for many years. It is very insoluble, nonirritating and almost tasteless and is therefore quite easily administered to children. It may be mixed with sugar to facilitate administration. It should be borne in mind that santonin is a toxic drug which may produce serious poisoning.

(a) *Preparation of the Patient*—The patient should be given a light evening meal at 5 p. m., no food being allowed after that.

(b) *Administration of Santonin*—At 10 p. m. the santonin should be given with an equal amount of mild mercurous chloride. Tablets containing one-half grain (0.03 Gm.) of santonin and an equal quantity of mild

20 Jamson Brown Robbins and Ward.<sup>11</sup> Molloy.<sup>11</sup> Brown.<sup>1</sup>

Although this substance will remove 85 per cent of *Trichuris* with a single treatment,<sup>17b</sup> it has the disadvantage that it ferments and becomes extremely unpalatable at ordinary temperatures. As doses of from 30 to 60 cc are given, it is not practical to conceal its taste by giving it in capsules. Because of the difficulty in shipping and storing, as well as because of its unpleasant taste, it has been used in this country only in a few experimental cases. Robbins<sup>21</sup> recently isolated the active principle of *leche de higueron*. It proved to be a proteolytic enzyme, which he has prepared in dried form and which retains its potency for a long time. This material has not been tried in patients, as Robbins found that it would attack and digest the stomach and intestinal mucosae when small lesions were already present.

#### PINWORM (*ENTEROBIUS VERMICULARIS*)

The life cycle of *Enterobius* is of the simplest type. Its eggs contain a larva when passed and require an incubation period of only twenty-four to thirty-six hours. On reaching the small intestine the ingested eggs hatch and the larvae are set free. The development of the larva takes place without migration through the body of the host. The worms grow to maturity in the small intestine, mate and then proceed to the large intestine. The adult female usually does not pass eggs but stores them in her uterus. The female, when filled with eggs, migrates out about the anus, causing an unbearable pruritus. These worms are broken open by the scratching of their host or by desiccation, and the enclosed eggs set free to be carried on the hands to the mouth.

#### TREATMENT OF PINWORM (*ENTEROBIUS VERMICULARIS*) WITH HEXYLRESORCINOL

Hexylresorcinol has been found<sup>22</sup> to be very successful in the treatment of pinworm. As this worm inhabits both the small and the large intestine, oral treatments and enemas are both necessary. Pinworms migrate to the anal region, usually at night, and the worms and eggs may be deposited on night clothes and bedding. For this reason any objects, such as night clothes, underclothes and bed sheets likely to be contaminated, should be boiled several times a week to kill the eggs. Small children should be warned about scratching the anal region, and their hands should be washed carefully after each toilet. In this infestation, personal hygiene is very important because of the fact that the worm eggs may be infective when passed and usually require only a twenty-four to thirty-six hour incubation period to become infective.

(a) *Preparation of the Patient*—A light evening meal is ordered the night before treatment.

(b) *Administration of Hexylresorcinol*—Since *Enterobius* lives in both the large and the small intestine, drugs used against it must be given both by mouth and by enema. When given by mouth alone the drug is often absorbed or diluted to such an extent as not to be present in effective concentrations in the large intestine. Treatments should be given every third day. The morning of the treatment no breakfast should be eaten and the drug should be taken at this time. The dose of hexylresorcinol is 0.1 Gm for each year of age. Thus

the adult dose of 1 Gm is given to every one 10 years or older. Care should be taken that the pills are swallowed and not chewed, for chewing the pills results in a superficial burn of the mouth and, though it is of no great consequence, it is very unpleasant.

Following administration of the pills the patient should be given a large, warm soapsuds enema to clean out the large intestine. Following this, an enema composed of 1 Gm of hexylresorcinol to 1,000 cc of water should be given and retained from five to fifteen minutes. This strength of hexylresorcinol is rapidly fatal to pinworms. Following the expulsion of this enema the anal region should be well dried, for to some the hexylresorcinol may cause slight irritation. The results of both enemas should be placed in a 40 mesh screen and washed with warm water and a search made for the pinworms, which are slender, pointed worms about one-half inch in length.

Following the oral administration of the drug the patient may go about his regular occupation. No food should be eaten for five hours following treatment, as it impairs the efficiency of the drug. Water or black coffee may be taken freely, and after five hours the regular diet may be resumed.

(c) *Signs and Symptoms of Toxicity*—These are described under hexylresorcinol treatment of ascariasis.

(d) *Contraindications*—These are the same as the contraindications in hexylresorcinol treatment of ascariasis.

(e) *Efficiency*—Patients who adhere to the advised hygienic precautions have been cured with one treatment. Children usually take longer, from three to five treatments being necessary. We have, by repeated treatments, cured every case of pinworm brought to the Vanderbilt Clinic. In case the enemas of two successive treatments contain no worms, treatments may be discontinued, to be repeated if worms are discovered later. Santonin oil of chenopodium, and tetrachloroethylene, given orally also remove numbers of pinworms.

#### TAPEWORMS

Beef Tapeworm (*Taenia saginata*), Pork Tapeworm (*Taenia solium*), Fish Tapeworm (*Diphyllobothrium latum*), Dwarf Tapeworm (*Hymenolepis nana*). The tapeworms found in man with the exception of *Hymenolepis nana*, require one or more intermediate hosts for the completion of their life cycles. The adult tenias live in the small intestine of man, their small heads buried in the intestinal mucosa. They have no mouth or digestive tract but absorb food through their body walls. They may grow as long as 15 feet. Each day or two the last segments of the worm are pinched off and may pass out alive and squirm about in the stool. These segments may be digested in the intestine, freeing into the stool their eggs, and these can be detected microscopically. Thus either eggs or segments or both may be found in the stool. These eggs, when eaten by a suitable host (the pig for *T. solium* or the cow for *T. saginata*), hatch in its intestine and migrate by way of the blood stream into the muscles and develop into tapeworm cysts. The cyst-containing flesh of these animals, when eaten insufficiently cooked by man, liberates the cyst, and the tapeworm head enclosed in each cyst attaches to man's intestine and grows into an adult tapeworm in from five weeks to three months.

The fish tapeworm, *D. latum*, passes eggs quite regularly. To complete the cycle these eggs must fall in water and be eaten by small water crustaceans, in which

<sup>21</sup> Robbins B. H. A Proteolytic Enzyme in *Leche de Higueron*, the Anthelmintic Principle of *Leche de Higueron*. *J. Biol. Chem.* **57**: 251 (June) 1930.  
<sup>22</sup> Brown H. W. Treatment of Pinworm (*Enterobius Vermicularis*) Infestation with Hexylresorcinol. *Proc. Soc. Exper. Biol. & Med.* **30**: 271 (Nov.) 1932.

the eggs develop into a larval stage. The crustaceans are eaten in turn by certain fish, and the larval tapeworms then migrate into their muscles and complete their larval development. Man develops an infestation when such fish are eaten raw or insufficiently cooked.

*Hymenolepis nana* (the dwarf tapeworm) is only several inches in length, but this is balanced by the fact that a person may harbor hundreds of them. Man acquires this tapeworm by ingesting the eggs, as no intermediate host is necessary for the completion of its cycle.

Aspidium has been handed down over a period of several hundred years as the standard drug used against tapeworms. McGath and Brown,<sup>23</sup> after the study of a series of cases, have reported a successful technique using aspidium against tapeworm. Recently, however, Daubney and Carman<sup>24</sup> and Maplestone<sup>25</sup> have shown that carbon tetrachloride is also very effective against tapeworm (*Taenia*). No other drugs have as yet been proved to be more valuable than these two in the treatment of these infestations, although hexylresorcinol will remove tapeworms in some cases.

#### TREATMENT OF TAPEWORM CASES WITH CARBON TETRACHLORIDE

Carbon tetrachloride was introduced in 1921 by Hall<sup>26</sup> for the treatment of hookworm and, although millions have been treated with it,<sup>3</sup> it is now being replaced, as already pointed out, by the much less toxic tetrachloro-ethylene. It would seem worth while to determine whether tetrachloro-ethylene could replace it in the treatment of tapeworm infestations.

Carbon tetrachloride, as previously pointed out, is a toxic substance which causes marked central necrosis of the liver even in therapeutic doses. Under certain conditions this action of carbon tetrachloride causes a marked increase of guanidine in the blood, which condition is normally neutralized by the calcium present.<sup>27</sup> If, however, the patient is in poor physical condition with a low calcium balance, the guanidine formed is not neutralized and the patient becomes severely intoxicated from carbon tetrachloride.

(a) *Preparation of the Patient*—Since one is unable by chemical analysis to determine whether the patient's calcium is low (as the blood calcium is not always an indication of this), to avoid intoxication from carbon tetrachloride the patient should be put on a high calcium diet from ten days to two weeks before treatment, and no meat should be given for a day or so before or after the administration of carbon tetrachloride. A light evening meal should be taken, but a preliminary purge has been found unnecessary.

(b) *Administration of Carbon Tetrachloride*—In the morning, breakfast should be omitted and carbon tetrachloride given early. Thirty grams of magnesium sulphate should be dissolved in half a glass of water and

the adult dose of 3 cc of carbon tetrachloride should be shaken up in this solution and swallowed. No breakfast should be allowed until the purge has acted. Following the action of the purge a warm soapsuds enema may be given and the stool examined for the head of the worm. Children may be given 0.2 cc of the drug for each year of age.

(c) *Signs and Symptoms of Toxicity*—In well nourished individuals there may be no symptoms or merely mild and transient feelings of warmth, with possibly some slight dizziness. In others a period of from twelve to twenty-four hours may elapse before any signs of intoxication occur, then the patient usually begins to vomit and vomiting continues uninterruptedly. Jaundice may appear and the patient may vomit and pass blood. Finally collapse may occur, death following in some cases. If marked intoxication occurs, calcium gluconate may be given orally or, in case it is impossible for the patient to retain substances given, intramuscular calcium gluconate may be given. In very severe cases intravenous calcium medication may be given but on account of the great danger of such administrations, in which overdoses may be instantly fatal, it is suggested that the subcutaneous method be given preference over intravenous administration.

(d) *Contraindications*<sup>28</sup>—The contraindication of utmost importance to the use of carbon tetrachloride is alcohol. So many cases of severe intoxication or death have followed the taking of alcohol at the time of the administration of carbon tetrachloride that there is no doubt whatever regarding the danger of this. As carbon tetrachloride injures the liver, one should avoid the giving of this substance in cases presenting liver disease. Patients with definite calcium lack should not be given carbon tetrachloride, but there has as yet been no definite method of ascertaining whether or not one is dealing with such a case. Therefore, the precautionary measures outlined should be followed before treatment is administered. If the routine treatment described is adhered to, the patient will not take fat immediately before or after treatment. It has been found in laboratory experiments and in the clinic that, when large amounts of fatty substances are taken immediately before or after treatment with carbon tetrachloride, absorption of this substance occurs probably through a different route than normally, carbon tetrachloride being carried around the liver through the lymphatics and reaching the brain in high concentrations, causing marked nervous symptoms not ordinarily seen.

Toxic symptoms seem to occur more frequently in persons treated with carbon tetrachloride when heavy *Ascaris* infestations are present and may be avoided by first treating the patient for *Ascaris*.

(e) *Efficiency*—Several workers<sup>29</sup> who have treated many persons harboring *Taenia saginata* report from 70 to 97 per cent success from this relatively simple treatment. *Taenia solium* is also removed by carbon tetrachloride. If the head of the tapeworm is recovered, it is fairly certain that the patient is cured, although multiple infestations of *Taenia* are not unknown. Even if large portions of the worm are recovered and the head is not, the stool must be found free from eggs or segments for several months before

<sup>29</sup> Daubney and Carman<sup>24</sup>, Maplestone and Mukerji<sup>25</sup>.

one can be sure that the treatment has been successful. Obviously, the head may have been digested or lost and the failure to recover the head does not necessarily mean that the patient has not been cured. Daubney and Carman, using this carbon tetrachloride treatment, found heads in only two of the thirty patients treated, yet seven weeks later only one of the patients began to pass segments again. The efficiency of this treatment for *Diphyllobothrium* and *Hymenolepis* has not been worked out.

#### TREATMENT OF TAPEWORM CASES WITH ASPIDIUM (MALE FERN)

*Aspidium* (male fern) has been the classic drug against tapeworm for years. Recently, McGath and Brown<sup>23</sup> instituted a technic at the Mayo Clinic with which they have been very successful in removing not only the common beef and pork tapeworms (*Taenia saginata* and *solum*) but also the fish tapeworm (*Diphyllobothrium latum*). Other workers report *aspidium* to be effective against *Hymenolepis nana*. *Aspidium* is not as nontoxic as it was formerly believed, and when given in large doses it is decidedly toxic and may be fatal.

(a) *Preparation of the Patient*—No luncheon or supper is permitted the day preceding the treatment. Black coffee, tea and water may be taken freely. At 6 p. m., from 15 to 30 Gm of magnesium sulphate should be given. The next morning at 6 a. m. an additional 15 to 30 Gm of magnesium sulphate should be given.

(b) *Administration of Aspidium*—The patient should be put to bed and allowed no breakfast. As soon as the purge given at 6 a. m. has resulted in a bowel movement (the stool should be examined for tapeworm) 30 cc of the following emulsion is administered: oleoresin of *aspidium*, 6 cc or Gm, powdered acacia, 8 Gm, water sufficient to make 60 cc.

One hour later the second 30 cc of the emulsion of *aspidium* should be given. (The amount given must be reduced when children are treated, a total dose of 4 cc of the emulsion for each 10 pounds (4.5 Kg) of body weight may be given. This dose corresponds to the 60 cc total amount for an adult of 150 pounds, or 68 Kg.) Two hours after this, 30 Gm of magnesium sulphate should be given in several glasses of water, to be followed in two hours by a large soap-suds enema. The stool resulting from the purge and enema should be passed into a container and examined for the worms.

(c) *Examination of Stool for Tapeworm*—The enema and all stools passed on the day of treatment should be poured into a 20 mesh sieve and warm water played on it and the fecal material washed away. The contents of the sieve can then be emptied into a flat pan (about 1 by 2 feet), the bottom of which has been painted black, and a careful search made for the tapeworm head. Brown and McGath, who recommend the *aspidium* treatment, report finding the head in the majority of cases.

(d) *Signs and Symptoms of Toxicity*—When moderate doses are used, mild poisoning may occur, as evidenced by a slight jaundice and complaint of vertigo and headache. In moderately severe cases, nausea, vomiting, abdominal pain and even bloody diarrhea are complained of. Yellow vision and sometimes temporary blindness may occur. In severe poisoning the patient becomes drowsy and often delirious. There may be

severe muscle cramps and convulsions, and respiration becomes shallow and the pulse weak. Because of the possibility of toxicity, the 6 Gm, as recommended, must not be exceeded.

(e) *Contraindications*—*Aspidium* should never be given to persons in poor physical condition. Because of its irritant properties, it should be avoided in cases of gastro-intestinal disease. It should be given with caution to pregnant women and in cases in which the kidneys are diseased. Oil purges should never be given, as they increase its absorption.

(f) *Efficiency*—McGath and Brown state that, by carefully following their technic, all their patients have been cured.

#### TREATMENT OF STRONGYLOIDES STER- CORALIS CASES

The life cycle of *Strongyloides* is similar to that of hookworm in that the larvae of both infect through the skin and migrate through the lungs before settling down in the intestine. The adult female *Strongyloides* is only one-eighth inch in length and buries itself in the mucosa of the intestinal wall. This protected position makes its expulsion by drugs very difficult.

Of numerous substances that have been tried, gentian violet has proved the most effective against this parasite. DeLangen<sup>30</sup> and Faust<sup>31</sup> have reported successful treatments of *Strongyloides* with this substance. Faust, who has treated 200 persons with this substance, recommends the oral administration of a one-half gram (0.03 Gm) enteric coated tablet three times a day to children of up to 10 years of age and a 1 grain (0.06 Gm) tablet three times a day for adults. The gentian violet is taken before meals for a period of from one week to ten days. A rest period of one or two weeks should be allowed between courses, during which time daily stool examinations should be made to ascertain the effectiveness of the treatment. Faust reports cures with one course of treatment in all but four cases, in which two courses were taken before a cure was obtained. Likewise, DeLangen noted marked relief in extremely severe cases of *Strongyloides* infestations in which from one-sixth to one-half grain (0.01 to 0.03 Gm) of gentian violet was given from three to five times a day. The dye stains the mucosa of the intestine a brilliant violet, and the adult parasitic worms living in the mucosa absorb the dye, which is very toxic to them.

Gentian violet has not been used extensively as an anthelmintic and relatively little information on its toxicity has been obtained. Faust<sup>32</sup> has shown that man and dogs tolerate daily oral doses of from 30 to 35 mg per kilogram of body weight. Young and Hill,<sup>33</sup> when treating septicemia and local infections, have given 500 mg of gentian violet intravenously to man. In view of the limited experience with gentian violet, patients to whom it is given should be observed carefully for any signs of toxicity, such as loss of appetite, nausea, vomiting or weight loss, and the drug temporarily discontinued if they occur.

33 Young H H and Hill Justina H. The Treatment of Septicemia and Local Infections. J A M A 82 669 (March) 1924.

Oil of chenopodium has also been recommended against *Strongyloides*

#### TREATMENT OF TRICHINELLA SPIRALIS CASES

The treatment of trichiniasis is made difficult by the fact that diagnosis in man is not usually made until several weeks after infestation, at a time when the invasion of the muscles by the young larvae has already begun. The treatment, therefore, must be directed against the young larvae circulating in the blood stream, those which have already entered the muscles, and the adult females buried in the intestinal mucosa. Miller, McCoy and Bradford<sup>34</sup> have shown that therapy directed against the larval stages is ineffective. They used neoarsphenamine, antimony and potassium tartrate, acriflavine, an acriflavine dye, gentian violet and metaphen intravenously without success. Likewise, treatment directed against the adult female buried in the intestinal mucosa is very unsatisfactory. If, however, a diagnosis is made while gastro-intestinal symptoms are still prominent, which indicates that the female worms are burrowing into the intestinal mucosa, the patient should be thoroughly purged with either castor oil or magnesium sulphate. This procedure will aid in the expulsion of the worms that are still free in the intestinal lumen and consequently reduce the number of larvae produced. One might even give a treatment of tetrachloro-ethylene or hexylresorcinol in the hope of killing the trichinellae only partially embedded in the mucosa.

### NONALCOHOLIC CIRRHOSIS OF THE LIVER IN THE LEBANON AND SYRIA

H. A. YENIKOMSHIAN, M.D., D.T.M. & H. (ENG),  
M.R.C.P. (LOND.)

Associate Professor of Internal Medicine American University  
of Beirut

BEIRUT, LIBANESE REPUBLIC (SYRIA)

Hepatic disorders are common in Syria and the Lebanon. In addition to the enlarged livers due to congestive heart failure and disease of the biliary tract, hydatid cysts and amebic abscesses of the liver are frequently seen. More frequently encountered is a third group of patients with hepatic enlargement associated with splenomegaly. The clinical features of this group are epigastric distention, irregular bowel action and drowsiness after meals. Many of the patients have had repeated febrile attacks associated with jaundice, often accompanied by transient hepatic enlargement, epigastric tenderness, nausea and vomiting, lasting from a few days to a few weeks. Many live a reasonably long life without marked evidence of liver insufficiency. Rowntree<sup>1</sup> says that their cirrhosis is probably compensated. A number sooner or later develop evidences of advanced portal cirrhosis with ascites.

Cirrhosis of the liver is seen more commonly at the American University of Beirut among clinic patients than among private patients. It is more frequent among the farmers than among city dwellers, and it is most frequently seen in the farmers from villages in the neighborhood of Sidon and Tyre.

#### CONDITIONS IN WHICH CIRRHOSIS IS MOST COMMON

The diet of the people consists largely of cereals, olives, citrus fruits, grapes and figs. Milk is never abundant and is never properly handled. Most of it is sold or else used only for the sick. The diet of the peasants is fairly adequate but is often poor in protein and vitamin A.

The principal article of food is bread made of whole wheat or a mixture of wheat, barley and corn flour. The farmers use also lentils, peas and beans. Olives and olive oil supply most of the fat. Butter is used after being boiled and stored for some time. Mutton is the principal meat. Chicken, beef and fish are eaten occasionally, but no pork is used. Green vegetables are consumed only during certain seasons, while oranges during the winter and grapes during the summer are rather abundant.

The average farmer smokes tobacco whenever he can afford it, but he rarely touches alcohol. The majority of the farmers belong to a sect of Islam that is strict on this point. The women never touch alcohol. These people do not use curry, their only condiments are red and green peppers, which are not used excessively.

Bacterial and protozoal infections and helminthic infestations are very common. Malaria, mostly of the tertian and estivo-autumnal types, and dysenteries are the prominent diseases and occur much more frequently among the farmers than among the urban population. Syphilis is not common, gonorrhea is rare. Typhoid is endemic. Follicular tonsillitis and rheumatic fever occur fairly frequently. Diphtheria is seen occasionally but there is no scarlet fever. Dermal leishmaniasis is frequent in certain sections, but only a few cases of infantile kala-azar have been detected. Helminthic infestations are very common, often two or more intestinal parasites are found in the same host. *Trichocephalus dispar* is almost always present, then, in order of frequency, occur *Taenia saginata*, *Ascaris lumbricoides* and *Oxyuris vermicularis*. *Ancylostomiasis* and filariasis are rare and there is no schistosomiasis.

The incidence of amebic dysentery is about equal to that of all types of bacillary dysentery, and double infections are not uncommon. Intestinal flagellates, such as *Giardia intestinalis* and *Trichomonas intestinalis*, are common. We have not been able to find *Balanitidium coli*. The cause of the diarrhea cannot be found in about one third of the cases.

#### CLINICAL CIRRHOSIS IN SYRIA AND THE LEBANON

During the six years from 1926 to 1931 inclusive I have studied in the medical wards seventy cases of portal cirrhosis with ascites.<sup>2</sup> Sixty-three per cent of the patients were less than 40 years, and 20 per cent were less than 20 years of age. Seventy per cent of the patients were male and 30 per cent were female. Only 8.8 per cent admitted the use, to a certain extent, of alcoholic drinks. Twelve per cent gave a history suggestive of syphilis or had positive Wassermann or Kahn reactions.

I have reviewed, for the purpose of comparison, the autopsy records of the cases of cirrhosis of the liver for the years 1925-1932 inclusive, at the Presbyterian Medical Center in New York.<sup>3</sup> There were forty cases

<sup>34</sup> Miller J. J. Jr., McCoy O. R. and Bradford W. L. Intra-venous Treatment in Experimental Trichiniasis. J. A. M. A. 98:1242 (April 9) 1932.

Read before the New York Society of Tropical Medicine March 9 1934.

<sup>1</sup> Chapman C. B., Snell A. M. and Rowntree L. G. Compensated Cirrhosis of the Liver. J. A. M. A. 100:1735-1741 (June 3) 1933.

<sup>2</sup> I am indebted to Dr. E. L. Turner, professor of medicine, Dr. G. B. Khayat, associate professor of medicine, and Dr. S. E. Harris, formerly associate professor of medicine, American University of Beirut for permission to include their cases in this group.

<sup>3</sup> I am indebted for this privilege to Dr. W. W. Palmer, professor of medicine, and Dr. J. W. Jobling, professor of pathology, Presbyterian Hospital, New York.

Only 13 per cent were younger than 40 years, and only 5 per cent were younger than 20 years. Eighty per cent were male. Fifteen per cent had syphilis, and 35 per cent had rheumatic or arteriosclerotic heart diseases. In 45 per cent, alcoholic drinks had been used over long periods. Apparently, cirrhosis of the liver occurs earlier in life and affects the female sex somewhat more frequently in Syria.

In Syria most of the patients with cirrhosis of the liver, except those with a chronic circulatory deficiency, show splenomegaly long before ascites appears. A history of malaria or dysentery or of both is especially common among the patients from the region of Sidon and Tyre. In 30 per cent, malarial parasites are found in the blood or in material obtained by splenic puncture, or a history of chronic malaria is obtained. Often by the time the cirrhosis is well established, the malaria has disappeared.

The duration of life varies from six months to five years after the first abdominal paracentesis. I know of patients who have been tapped twenty, forty and even seventy times. Frequently, palpation shows that the liver is hard and irregular and it remains enlarged to the end. Analysis of the gastric juice frequently shows low acidity, the icterus index is but slightly elevated, the levulose tolerance is lowered in some cases and the blood calcium is somewhat low, varying from 8 to 10 mg per hundred cubic centimeters.

Often marked jaundice and anuria develop a few days before death, but the blood urea does not rise markedly. The patients become extremely emaciated before death. A large hard spleen and a distorted coarsely hobnailed liver, usually enlarged but occasionally atrophic, are found at autopsy. Unfortunately, permission for an autopsy cannot always be obtained.

#### COMMENT

Notwithstanding the many obscure points regarding the etiology and pathogenesis of portal cirrhosis, it appears certain that there must be repeated injury to and degeneration and necrosis of liver cells, not extensive enough to produce the immediate death of the subject. The injury is followed by inflammation, regeneration and fibrosis, the end results being determined by the interplay of these processes. Furthermore, although single injuries may suffice to produce cirrhosis in experimental animals, a combination of toxic and infectious agents acting simultaneously or in sequence is more potent and is perhaps the usual sequence of events occurring in the production of human cirrhosis.

A prolonged study of the cases has convinced me that chronic malaria and dysentery, and especially the combination of the two, are the important factors in the causation of the type of cirrhosis seen in Syria. An enlargement of the liver accompanied by jaundice, epigastric tenderness and vomiting occurs frequently during the course of malaria. In fact, most patients with the large spleen of chronic malaria have also a large liver. Knowledge of the pathologic anatomy of human malaria is based on autopsies of patients dying from pernicious attacks of estivo-autumnal malaria. Deposition of pigment in the Kupffer cells, thrombosis of hepatic capillaries, degenerative changes in the liver cells and occasional areas of necrosis are the changes most commonly found. Most pathologists emphasize the fact that fibrosis is absent in these livers.

The change that occurs in the damaged livers of the many patients who recover is a matter for speculation. It is known that the malarial pigment remains in the Kupffer cells for a certain length of time after the patient recovers from the attack. Unless the patient is properly treated, and protected against further infection, the malaria becomes chronic, and with each recrudescence there must occur a new insult to the liver and new areas of degeneration. Perhaps the end result of these oft repeated injuries to the liver will be determined some day from studies of experimentally produced malaria.

Diffuse hepatitis without demonstrable abscess formation is not an infrequent manifestation of amebiasis. Patients with slight jaundice associated with an enlarged and tender liver, nausea and vomiting, slight fever and leukocytosis are assumed too frequently to have catarrhal jaundice. I have seen such cases in which, in spite of the absence of a history of dysentery, examination of the stools revealed cysts of *Endamoeba histolytica* and suitable treatment brought prompt relief. I believe that these attacks of hepatitis entail repeated periods of degeneration and necrosis in the liver, alternating with periods of regeneration and repair. The end result of such processes, continuing unchecked can only be imagined. The possibility that cirrhotic changes will appear in a liver is probably enhanced in the cases in which malarial infection and amebic infection occur alternately or together. Ewing<sup>4</sup> has reported advanced degenerative changes in the liver cells in a case of double infection with malarial plasmodia and *Endamoeba histolytica*.

Ascariasis *lumbricoides* is much more prevalent among the inhabitants of the city of Aleppo, in whom cirrhosis is not seen so frequently as it is among the farmers.<sup>5</sup> Professor Bonne of Java tells me that in that country cirrhosis of the liver is not more frequent among the people who harbor *Taenia saginata*.

The poor farm laborer of the district of Sidon and Tyre receives treatment of his malaria and dysentery which is inadequate in comparison with that received by the town dwellers. This may be another reason why cirrhosis is more common in these rural communities.

#### SUMMARY

Cirrhosis of the liver is of frequent occurrence in Syria and the Lebanon. It is more common in the rural population than in the dwellers in cities. It is particularly frequent in the farm laborers in one district near Sidon and Tyre.

Alcohol is not used by these people and they do not use condiments excessively, syphilis is uncommon, but malaria, dysentery, and infestation with intestinal parasites are prevalent.

The cirrhosis is seen in comparatively young people, 63 per cent of the patients being younger than 40 years. The proportion of female patients with the condition is larger in Syria than in America. Enlargement of the spleen is marked and often precedes signs of liver insufficiency. The liver often remains enlarged and coarsely hobnailed.

Malaria and amebic dysentery (and especially the combination of the two) seem to be the primary causes of cirrhosis of the liver in Syria and the Lebanon.

## SPASTIC PARAPLEGIA

CASES ILLUSTRATING THE COMMON ETIOLOGIC  
FACTORS

N W WINKELMAN, MD

PHILADELPHIA

AND

JOHN L ECKEL, MD

BUFFALO

Spastic paraplegia is a descriptive term and not a diagnosis. Its causes are many. In the classic form it is characterized by a progressive spasticity in the lower limbs, with all the signs and symptoms of a pyramidal tract disease below the level of the lesion. The onset is described by the patient in terms of fatigability of the lower limbs. This fatigue of the muscles is the result of a beginning "muscular ankylosis of the joints," as Strumpell<sup>1</sup> designated it, in its later stages.

While the symptomatic recognition of a spastic paraplegia is relatively simple, the etiologic factor is usually difficult to discover. The older writers frequently limited the term spastic paraplegia to a rare group of cases first described by Erb<sup>2</sup> and Charcot,<sup>3</sup> which is now designated as primary lateral sclerosis. This condition occurs mainly in children and young adults and a progressive spastic paralysis beginning in the lower limbs is the only symptom of the disease. In the great majority of cases of this kind, however, the progress of the symptom complex discloses the fact that some other condition is basically responsible for the spastic weakness in the lower limbs, and, further, the signs and symptoms are usually not limited to the pyramidal tracts.

Given a patient with a beginning spasticity in the lower limbs, with pyramidal tract signs, including mild bladder involvement, with or without sensory changes, careful study is necessary to determine the basic pathologic process. Many of the European writers<sup>4</sup> have placed multiple sclerosis as the most common condition showing spasticity in the lower limbs as its earliest manifestation. Most of the cases diagnosed as primary lateral sclerosis which have come to autopsy have shown the plaque formation which is characteristic of multiple sclerosis. In fact, a spastic paraplegia may be for years the only evidence of a multiple sclerosis, even with apparent level signs. The following case illustrates this condition.

A physician, aged 40, with bronchiectasis, began to show progressive spasticity in the lower limbs, without bladder symptoms. A careful study revealed a sensory level at the sixth thoracic segment with a complete block as shown by the Queckenstedt test and injection of iodized oil. Laminectomy revealed no cause for the symptoms. The patient, however, became completely paraplegic immediately after the operation and remained so for a period of six years. Treatment for the bronchiectasis was carried on during all this time. With improvement in the lung condition the neurologic picture became markedly improved, although recently the lung condition has been worse. The patient is now able to walk, but

there is still mild spasticity, hyperreflexia, clonus and a positive Babinski sign. The sensory disturbances are now in the background.

This case had originally suggested spinal cord tumor and the operation was done because of this diagnosis. Nothing was found to explain the condition and nothing was done to account for the immediate complete paralysis or the improvement six years later. The serologic examinations have always been negative and no antisyphilitic treatment was given. At the present time multiple sclerosis is the most plausible diagnosis even in the absence of signs and symptoms above the sixth thoracic segment, because of an almost complete remission that has now lasted nearly two years. It is usual to have disturbance in deep sensibility in multiple sclerosis in addition to the spasticity. This our patient had, but it has completely disappeared.

Syphilis must always be considered as an etiologic factor in progressive spasticity of the lower limbs. As a rule it originates from the meninges and involves the spinal cord substance secondarily, with the formation of what is histologically a syphilitic meningomyelitis. Intramedullary syphilitic lesions of the spinal cord occur in the nature of a vascular disease<sup>5</sup> and gummas are rarely seen. This syndrome is well illustrated by the following case.

A physician, aged 53, complained chiefly of increasing weakness and spasticity of both lower limbs. There were no symptoms or signs referable to the upper half of the body. Examination showed a sensory level at the eighth thoracic segment with a spastic paraplegia. A gross cord lesion was suspected. The Queckenstedt test confirmed our suspicion, an almost complete block being found. Despite positive serologic results in both blood and spinal fluid, the patient demanded an exploration. A focal meningomyelitis was discovered at the diagnosed level. Surgery could do nothing for him because of the firm adherence of all the membranes to the spinal cord with invasion of the cord substance. Therapeutic measures have produced only a mild improvement. This is usually the case when destruction of the fiber tracts has already occurred.

Cases of this sort are not rare, but the classic picture produced by a focal syphilitic process is the so-called Brown-Sequard symptom complex. This is characterized in brief by motor paralysis on the side of the cord lesion, with sensory disturbances of pain and temperature on the contralateral side below the level of the lesion. This syndrome can also be caused by any unilateral lesion involving the spinal cord.

Pernicious anemia is notorious for its effect on the spinal cord. The condition, when typical, is so characteristic that it can frequently be diagnosed before the blood changes occur. A combined degeneration is the rule. Clinically this is shown by motor weakness, with spasticity, at times, and with posterior column disturbance mainly involving vibration and muscle position. This condition is illustrated by the following case.

A woman, aged 59, showed spasticity in the lower limbs as the predominant symptom. Because of the presence of ataxia with loss of vibration in the affected limbs, pernicious anemia was suspected. Gastric analysis showed complete absence of free hydrochloric acid. The results of the examination of the blood confirmed the clinical diagnosis. Treatment with liver and hydrochloric acid produced only a very mild improvement because of the degree of involvement of the cord substance.

As a rule the onset of spinal cord changes is shown clinically by paresthesias in the fingers and toes, with clumsiness in finer movements and with weakness in the lower limbs with or without spasticity. A combination of paresthesias and pyramidal tract signs with posterior column symptoms is extremely suggestive of pernicious anemia.

Trauma can produce changes in the spinal cord, as it does in the brain, the result of concussion, hemorrhage or incision from compression. The clinical picture usually begins shortly after the trauma, with flaccidity in the beginning which rapidly changes to spasticity if the lesion is not a complete transverse myelomalacia. This is illustrated by a patient who was "jack-knifed" in an attempt to "jack up" an automobile. The paralysis in the lower limbs was complete and flaccid in the beginning. Gradually spasticity developed, with the permanent residuals showing an incomplete transverse lesion of the spinal cord.

Vascular lesions of the spinal cord occur with sufficient frequency to receive attention. They are seen in both young and old. They often come on abruptly and produce symptoms in direct relation to the size of the vessel involved and its location. A recent case will illustrate the symptomatology in young people.

A boy, aged 13 years, after recovery from a grippal infection carried a heavy weight for a short distance. A few hours later he experienced pain in the lower chest, anteriorly, which caused him to rest for a few hours. On awakening he found that he was paralyzed from the waist downward. A sensory level could be established, more marked for pain and temperature than for deep sensitivity. A gradual improvement is occurring but the patient will probably not make a complete recovery. The vessel involved in this patient was probably the anterior spinal artery.

In older people, arteriosclerosis and syphilis play the dominant roles. We have discussed this subject in detail in previous publications.<sup>6</sup>

Intramedullary or extramedullary tumors of the spinal cord are capable of producing a spastic paralysis in the lower limbs if they are situated below the cervical enlargement. Frequently the first complaint is tiredness, the result of spasticity and weakness in the lower limbs, which may progress to a complete paraplegia. Symptoms of a level lesion are frequent with root irritation including the so-called girdle sensation and a sensory level. The extramedullary tumors are theoretically capable of producing root symptoms more frequently than the intramedullary ones. From the practical standpoint, however, it may be impossible to differentiate them clinically. A word of caution might be interpolated at this point in regard to the Queckenstedt test. We saw a marked increase in the spinal cord symptomatology, including the onset of a complete paralysis, develop in a patient as the result of the performance of this test. According to Elsberg,<sup>7</sup> the sudden onset of paraplegia following a Queckenstedt test is in favor of an extramedullary and frequently an extradural lesion. In one patient in whom this occurred, the autopsy disclosed an intramedullary tumor of the spinal cord.

Tuberculosis of the spine is a well recognized etiologic factor in the production of spastic paraplegia. The vertebrae may or may not show gross deformity. The roentgenogram will frequently show the bone disease. At times an extradural granuloma without Pott's disease is seen. Intramedullary tuberculoma is extremely rare. We have seen it in only three cases. The symptomatology does not differ from that of other intramedullary gross lesions.

In nontuberculous lesions of the spine, the spinal cord can be eventually compressed with the production of a spastic paralysis in the lower limbs.<sup>8</sup> Such conditions have been described by Viets and Clifford<sup>9</sup> in a kyphoscoliosis. In this group might be placed extradural abscesses and metastatic lesions of the dura.<sup>10</sup> In the abscess cases the history is usually characteristic. There is frequently a preceding boil or carbuncle on the back of the neck with the sudden onset of spinal cord symptoms, including root pains and paraplegia, either flaccid or spastic. Abscesses within the cord itself are rare, only a few cases having been reported.<sup>11</sup>

Unfortunately, metastatic lesions to the spinal cord membranes from the breast and the prostate are comparatively common. Transverse spinal cord symptoms are the rule. Frequently the site of preference is outside the dura. They have been known to produce sudden paraplegias. Spiller<sup>12</sup> was the first to call attention to this fact. We<sup>6</sup> have also reported similar cases.

No discussion of spastic paraplegia is complete without a mention of hysteria, which may so mimic an organic cord disturbance that it may be difficult at first to make a differentiation. The presence of organic signs should serve to make the correct diagnosis.

The infectious diseases play an important role in the production of spinal cord involvement, particularly in children. We have recently seen spastic weakness and incoordination in the lower limbs following measles. Most of these cases clear up completely. Other childhood diseases can produce similar pictures. As a rule the spinal cord involvement is not complete and in the later stages the patients show only weakness and incoordination. In the adult a spastic weakness can occur from infections and from serums and vaccines.<sup>13</sup>

Lesions of the paracentral lobules of the brain can give a spastic weakness confined to the lower limbs that simulates spinal cord disease. Such a case is portrayed by a patient, aged 52, who began to show weakness of both lower limbs, associated with rigidity and poor control of the sphincters. Sensory disturbances were not prominent. On admission, marked spasticity and hyperreflexia of the lower limbs were noted. The serology was negative. There were no signs of intracranial pressure. The patient lived only two months after the onset of the condition, death being due to cardiovascular disease. At autopsy the brain showed a large fibroblastic tumor springing from the falx cerebri and compressing and destroying both paracentral lobules.

A less common condition giving a symptom complex that can be described by the term "spastic paraplegia" is arachnoiditis, described particularly by Stookey.<sup>14</sup> Recently cases have appeared in the literature which give evidences of a gross focal lesion with spastic-ataxic paraplegia in which at operation only an adhesive process in the meninges is found. Stookey has found this syndrome in a series of well studied cases. Their differentiation from spinal cord tumor is difficult and at times impossible.

## COMMENT

We have enumerated a group of conditions in which spastic paralysis of the lower limbs is the predominant picture. We have, however, by no means exhausted the list. While the recognition of the symptomatology is easy, the determination of the etiologic factor is usually difficult. Certain conditions occur particularly in certain age groups, yet no age is exempt. Even in children metastatic cord lesions occur, such as sarcoma, hypernephroma and Hodgkin's granuloma. Arteriosclerosis is not common in the young, yet thrombosis of the anterior spinal artery is more common in the young than in the old.

Syphilis plays a dominant role in spinal cord disease. Even when gross lesions are suspected, one must keep this etiologic factor in mind. Unfortunately when many cases of syphilis of the spinal cord are recognized the condition has advanced so far that therapy can only prevent progression of the disease and cannot effect a cure.

We have seen severe cord symptoms of the spastic-ataxic type as an allergic reaction. We have seen a spastic paralysis after the use of antirabic vaccine and after the use of serums and vaccines of all sorts. While some of these cases tend to recover, many show severe residuals.

While the term spastic paraplegia refers most frequently to involvement of the pyramidal tracts, it is extremely uncommon to see pure cases of this sort. There is usually involvement of the sensory pathways with resulting ataxia and disturbance of sensation up to the level of the lesion. The sphincters are involved in direct relation to the motor and sensory disturbances. The diagnosis of a primary lateral sclerosis is usually incorrect. The cases which have come to autopsy with this diagnosis have been multiple sclerosis, tumors, vascular lesions or other pathologic conditions. We have seen, however, a case in a young patient whose brother and father also had the type that is recognized as the familial form of primary lateral sclerosis.

Because of the peculiarities in the circulation, sclerosis of the vessels in and around the cord is not as frequent or as early as is atheromatous change in the vessels of the brain. Yet the cord is not immune to sclerosis of its vessels. The peculiarity of the circulation is due to the fact that all the vessels destined for the spinal cord come off at right angles to the parent branches. The rarity of metastatic lesions of all sorts to the spinal cord itself is testimony to the fact that the vessels are not in the direct line of blood flow. Metastasis to the membranes of the cord, however, is common.<sup>6</sup>

As indicated before, the list given is by no means complete. Rare conditions can occur, such as diabetes mellitus, early amyotrophic lateral sclerosis, leukemic infiltrations,<sup>10</sup> myelomas,<sup>10</sup> Caisson's disease<sup>4</sup> (Oppenheim<sup>4</sup>) and paraplegia of the aged.<sup>4</sup> Sudden and severe generalized hemorrhages rarely if ever produce spinal cord involvement, in contrast to pernicious anemia. Spinal cord involvement has also occurred after severe systemic infection. It has been seen in hemangioma of the spinal cord.<sup>17</sup>

Given a case of beginning spastic weakness in the lower limbs, what is the method of examination and what are the possibilities in order to determine the underlying basis? A complete history is essential. A thorough neurologic study must be done. Serologic and cytologic studies of blood and spinal fluid are important. The Queckenstedt test should be done as a routine procedure in every case of involvement of the spinal cord that even suggests a gross lesion. Roentgenographic studies of the spinal column may give diagnostic information. Search for primary malignant lesions should be carried out on the least suspicion that the spinal cord symptoms are the results of metastasis.

While it is impossible to list the various conditions that may produce spastic paraplegia, a good working list has already been given.

## SUMMARY AND CONCLUSIONS

1 Spastic paraplegia is a descriptive term and not a diagnosis.

2 The term primary lateral sclerosis is now given to the group originally described by Erb and Charcot, in which only the pyramidal tracts are involved. These cases are extremely rare. Many occur in children and are familial.

3 Most of the cases beginning with spastic weakness in the lower limbs prove to be either multiple sclerosis, syphilis, pernicious anemia, neoplasm, trauma or other conditions.

4 Thorough study is needed in all cases presenting a beginning spastic paraplegia to make an etiologic diagnosis.

## ABSTRACT OF DISCUSSION

DR I S WECHSLER, New York. I can subscribe to every word Drs Winkelman and Eckel said and yet take exception to the whole paper. By this I mean that they have given a title that tries to cover everything and therefore, I fear, covers nothing. Spastic paraplegia is a designation that has come down from writers of fifty years ago, who did not have the knowledge of pathology or of clinical neurology that exists today. The term used to cover a multitude of conditions now recognized as specific syndromes. If by spastic paraplegia is meant only involvement of the pyramidal tracts, of course many of the conditions that the authors enumerated are either not described sufficiently or are described too extensively. It seems to me that they tried to cover the symptomatology of the spinal cord. As a nosologic entity the term "spastic paraplegia" no longer has any place in neurology. With injury of any sort to the spinal cord not necessarily that of trauma but of infection, tumor, tuberculoma, vascular diseases or what not, the important question is: What happened to the cord and where has the lesion taken place? An injury at a given level involves various pathways, depending on the extent of the lesion and on the rapidity of its development. It doesn't matter so much what happens to the cord, much more important is where and how severely it has been affected and what the etiologic or pathologic process is. If, for instance, there is a tumor, all the symptoms point to a level and below it. Similarly with a crush of the cord. If there are disseminated lesions, such as occur in infections, multiple sclerosis or syphilis, one is not dealing with a spastic paraplegia or with a cord condition alone. Therefore it seems to me that it is much better to know the lesion, know its location, estimate its extent, and then find out whether there are sensory changes, pyramidal tract signs, vasomotor disturbances, vesical and rectal disturbances, and so on. While I agree in the main with what Drs Winkelman and Eckel have said I think it would be much better to throw out the whole concept of spastic paraplegia and speak of the clinical syndromes in anatomic, physiologic, pathologic and etiologic terms.

DR N W WINKELMAN, Philadelphia Dr Wechsler's point of view is exactly the point of view we have tried to give, that spastic paraplegia is a descriptive term. It is, however, a term that is used even by neurologists and is not an accurate histopathologic diagnosis by any means. That is the whole point of the paper, as we have stated. We have given a short outline for the general physician, which he may use whenever a patient with a spastic weakness in the lower limbs presents himself for diagnosis.

## CHRONIC BRUCELLOSIS

ALICE C EVANS, M.S.

Senior Bacteriologist National Institute of Health United States  
Public Health Service  
WASHINGTON, D. C.

Brucellosis is the most recent, and it appears to be the most satisfactory, name applied to *Brucella* infections. "What's in a name?" As it will be pointed out later, names have been very important in shaping the history of this disease.

Hughes,<sup>1</sup> who in 1896 gave the name "undulant fever," understood the importance of the name. He published in the *Lancet* an entire article on the subject of an appropriate name for this disease. He covered almost half a column with the enumeration of the many names which down to that time had been applied to the disease in various languages. Since he wrote that article still more names have been applied. Mediterranean fever, Malta fever and undulant fever have been the most commonly used.

The only amusing incidents that I know to have been associated with the dreary disease have been connected with the name. According to a story related by Hughes, the British military reports used to designate the disease as "simple continued fever." The Tommy, who apparently liked the alphabet as well as do Washington officials, reduced the name to "S. C. fever." Then, forgetting what the S stood for, he evolved "slow continued fever," which had the advantage of expressing his feelings somewhat. Hughes conceded that "slow continued fever" was as good a name as any, with the exception of the new one of "undulant fever," which he then proposed—"undulant" referring to the wavelike appearance of the temperature curve. Later it will be pointed out that undulant fever is not an appropriate name for the disease as it is now known.

It is somewhat amusing to look back on the exasperation of the native Maltese over the use of the name of his island to designate this disease. To stigmatize his native land in that way was too much for him. The *Lancet* is responsible for this little pun. To the question "How would you make a Maltese cross?" the answer is "Associate the name of the island with a disabling fever."

Sympathetic with the Maltese, the International Congress of Medicine and Hygiene meeting in London in 1913 adopted a resolution to abolish the name Malta fever and substitute "undulant fever," as proposed by Hughes. But still the name stuck. Again in 1927 official action was taken. The Malta branch of the British Medical Association reprimanded American and continental writers for their persistence in the use of the odious name. It is now gradually passing into

disuse, probably not so much as the result of official remonstrance as because of a realization that a local name is not appropriate for a disease of world-wide distribution.

The name brucellosis is preferable to all others because it simply expresses infection with *Brucella*, regardless of the nature of the disease response, and because it is applicable to the disease in man or in any of the lower animals.

There was also a significant confusion of names in regard to the causal organism. In 1886 Bruce, a medical officer in the British army stationed on the island of Malta, discovered the causal organism of the fever that disabled many of the soldiers of the garrison on that island. He called the organism *Micrococcus melitensis*.

About a decade later the Danish veterinarian Bang discovered the causal organism of contagious abortion of cattle, a disease that ranks with tuberculosis in causing tremendous financial losses to dairymen in every country of the world where cattle are raised. Bang named his organism *Bacillus abortus*.

These two generic names, *Micrococcus* and *Bacillus*, served for two decades to guide bacteriologic investigations of the human disease and the disease in cattle into separate channels. Then in 1917 I happened to be studying the bacterial flora of milk as it comes from the cow's udder and found that Bang's bacillus is very closely related to Bruce's micrococcus. Later the generic name *Brucella*, derived from Bruce, the name of the discoverer, was given to the entire group, including the organisms of Bruce and of Bang. The causal organisms of the human and bovine diseases were found to be so closely related that it was a mystery why a disease similar to the so-called Mediterranean fever was not known in this country.

The war, with its special problems, diverted interest from *Brucella* investigations until 1922, when the first case of human infection with the abortus variety of the organism was diagnosed in the Johns Hopkins Hospital. It was reported by Keefer in 1924.<sup>2</sup> Subsequently, as physicians have gradually learned that brucellosis is a disease that should be considered in every case of fever not attributable to other causes, the number of reported cases has greatly increased. Last year there were 1,787 cases reported in the United States, some from every state of the union. It is not known what percentage of the total number of cases the reported cases represent. It is certain that a great number of cases of *Brucella* infection are not recognized as such.

Brucellosis is a very deceptive disease. The symptoms are manifold, sometimes resembling one disease and sometimes another. Even in Mediterranean countries, where the disease is of a severe type and where it has been known for many decades to occur commonly, the diagnosis is often incorrect. In 1922, before human infection with the bovine type of the organism was known to occur, Bassett-Smith<sup>3</sup> made the statement that in its early stages nearly every case of brucellosis had been treated for some other disease before the correct diagnosis was made. Every treatise on brucellosis emphasizes the extreme difficulty of diagnosis, owing to lack of characteristic symptoms. Typhoid, malaria, rheumatic fever, endocarditis, tuber-

Read before the Alumnae Association of the Woman's Medical College of Pennsylvania, Philadelphia, June 5, 1934.

culosis, bronchial pneumonia, bronchitis and influenza are some of the diagnoses erroneously given to acute cases of brucellosis.

During the last few years the physicians of this country have become alert to the prevalence of brucellosis, and it seems probable that now most of the acute cases that come into the hands of competent physicians receive the proper diagnosis. But there is convincing evidence that cases of the milder forms of the disease rarely receive a correct diagnosis.

The writers who described brucellosis in Mediterranean countries recognized mild types of the infection as well as the severe types. Shaw,<sup>4</sup> who was a member of the British Mediterranean Fever Commission of 1905-1907, was the first to recognize the so-called ambulant form of the disease, in which symptoms may be entirely absent or limited to a few days of slight fever. Shaw discovered the ambulant type of cases by examining the blood of 525 Maltese dockyard employees for specific agglutinins in the blood serum. Fifteen per cent gave a distinct reaction and twenty-two of those giving the highest agglutinin titer were examined carefully. Cultures were obtained from ten, all of whom were working full time. Examination revealed, however, that there was a slight rise of temperature in some of them.

Shaw's observations on the ambulant form of the disease have been confirmed by other investigators in other parts of the world. Hardy<sup>5</sup> and his collaborators reported that an average of 25 per cent of the cases they studied in Iowa were ambulant. The one constant symptom, and occasionally the only one, was weakness. Physical examination usually revealed no abnormality.

Of special interest are the recent reports of investigations on packing house employees in this county.<sup>6</sup> The porcine type of *Brucella* is more virulent for man than is the bovine type, and the handling of infected material leads to infection more readily than does the ingestion of contaminated food. Hence, packing house employees who handle hog products work under conditions peculiarly hazardous for contracting brucellosis, and a study of such groups has been a fruitful field for investigation. The results of the several investigations have agreed in showing that individuals who come into contact with infective material may develop immunity reactions without suffering any notable illness. Further, the results of the studies have revealed that even among packing house employees—a group whose illnesses should promptly suggest brucellosis—a large percentage of cases do not receive a correct diagnosis. Among the packing house employees examined by Martin and Myer, fifteen cases were found with histories of illness suggestive of brucellosis during the preceding eighteen months and with agglutinins specific for *Brucella* in the serums. Only three, or 20 per cent, of the fifteen cases had received a diagnosis of brucellosis.

If only 20 per cent of cases of brucellosis receive a correct diagnosis in a group in which occupational hazards should suggest infection with *Brucella*, it seems

probable that sporadic cases with less obvious histories of contact with the organism may receive a correct diagnosis in an even smaller percentage of cases.

The name "undulant fever" is an obstacle to the recognition of some of the chronic cases, for it implies a fever temperature, whereas that does not always obtain. There is to be found in the literature little information about the disabling chronic form of the disease in which, during long periods of many months of illness, there may never be a significant rise in temperature.

In his classic monograph of 1897 on undulant fever, Hughes<sup>7</sup> describes what he calls an intermittent type of the fever in which the temperature may be normal or subnormal in the morning, 99 F or higher in the afternoon, and normal again at night. He mentions that this condition, with mild symptoms of disease, may continue for months. Hardy and his associates in their paper of 1930 on the disease in Iowa state that in their ambulant cases the temperature was normal in the forenoon and rarely reached 101 in the evening. But neither Hughes nor Hardy emphasizes the fact that in a given case the slight afternoon rises in temperature may continue to be insignificant for months. In my own case, on more than one occasion there were many months of complete disability with never a rise of temperature above 99.5 F.

The recent investigations of Feldman and Olson<sup>8</sup> are a valuable contribution to the knowledge of chronic brucellosis. These authors availed themselves of slaughter house material for the study of the chronic disease in swine. They selected for study apparently healthy animals that gave positive agglutinin reactions. From one of these animals, in which postmortem examination revealed no lesions, the causal organism was obtained from the spleen. From another hog carcass *Brucella* was cultivated from an abscess of the spermatic cord and also from the lymph nodes of the head, although the lymph nodes did not reveal morbid changes. These investigators studied a number of cases of spondylitis in apparently normal slaughter house hogs. They demonstrated *Brucella* in some of them. It was usually the lumbar or sacral vertebrae that were affected. The result of this study of spondylitis in swine is of particular interest from the point of view of the human disease, because lumbar pain without objective signs of the disease is a common symptom in cases of human *Brucella* infection. Spondylitis in man, proved to be due to an abscess caused by *Brucella* infection, has been reported.<sup>9</sup>

Results similar to those of Feldman and Olson have been obtained by many other investigators of the disease in various domestic and experimental animals. There have been repeated demonstrations of infection in cattle and goats without clinical evidence of disease. In fact, the great difficulty in avoiding the use of milk contaminated with *Brucella* is that these organisms are excreted in the milk of apparently healthy animals.

Since the infection occurs commonly in animals that show no sign of disease, and since it is even known to occur when lesions are not to be found on postmortem

examination, an explanation for the difficulty in diagnosis of the human disease is at hand

I shall draw from my own experience certain conclusions as to the diagnosis that the patient with the chronic form of the disease generally receives. I have been consulted by a number of patients with the chronic form of the disease who have been fortunate enough to receive, finally, the correct diagnosis. Usually there was a long delay before the correct diagnosis was given, and in the meantime the diagnosis was almost invariably neurasthenia. Indeed, the textbook definition of neurasthenia describes chronic brucellosis: exhaustion, insomnia, irritability, and complaints of aches and pains for which no objective signs can be found.

It is a severe trial for the brucellosis patient, which contributes largely to the mental depression characteristic of the disease, that when he appeals for medical aid he is told that his illness is only imaginary and that all that is necessary for his recovery is that he should acquire the proper mental attitude.

There is no doubt that chronic brucellosis is often diagnosed as neurasthenia. Hence, an important problem presents itself: What percentage of the great number of cases of so-called neurasthenia is due to Brucella infection?

A study of a large group of cases which have been diagnosed as neurasthenia should yield information on that point. It cannot be expected, however, that clinical study will give the desired information, for the diagnosis of neurasthenia in any given case was made because the physicians who examined the patient were unable to find a demonstrable cause of the disease. Further, the fact that characteristic symptoms are lacking in acute cases and the knowledge of the disease in apparently healthy animals discourage the idea that clinical examination of chronic cases may lead to a correct diagnosis. It is necessary to resort to special laboratory tests.

The one infallible proof of Brucella infection is the cultivation of the organism from the blood or excretions. Cultures are frequently negative in acute cases, however, and there is a poor chance to obtain a culture from chronic cases.

A positive agglutinin reaction is suggestive of Brucella infection in a patient with undiagnosed disease. Consideration must always be given, however, to the fact that sometimes normal individuals respond to Brucella infection by the development of agglutinins in the blood without accompanying illness. On the other hand, negative agglutinin reactions are of little significance. Even in severe cases, in which Brucella infection is proved by cultivation of the organism, agglutinins may be lacking in the serum. That was true in my case, and Carpenter, Boak and Chapman<sup>10</sup> have recognized severe cases presenting a weak titer of agglutinins or none in the serum. Burnet<sup>11</sup> reported that 16.6 per cent of his cases failed to show agglutinins in the serum, and Simpson<sup>12</sup> reported a number of such cases. Infection without the occurrence of agglutinins would be even more likely to occur in mild

than in severe cases. Hence, a negative agglutinin reaction cannot be regarded as significant in chronic cases.

Because of the limitations of the agglutinin test a number of investigators have studied the possibility of detecting Brucella infection by means of cutaneous reactions following injection of various preparations derived from Brucella cultures.<sup>13</sup> They all concluded that the intradermal tests are useful in detecting Brucella infection. In interpreting the results of cutaneous tests, however, consideration must be given to the fact that normal persons may develop cutaneous hypersensitiveness without symptoms of illness as a result of Brucella infection and that cutaneous sensitiveness remains after recovery from brucellosis.

Since none of the three mentioned tests for the detection of brucellosis give results that may be interpreted as definitely positive or negative evidence of brucellosis, a consideration of the combined results of all three tests is the best procedure now available for the diagnosis of this disease. Huddleson, Johnson and Hamann<sup>14</sup> suggest that a fourth test, the opsonic power of the blood, be included. The practicability of their suggestion has not as yet been confirmed.

In considering the incidence of chronic brucellosis in this country it is pertinent to consider the distribution of the causal organism. It exists in every country where cattle are raised and is excreted in the milk of infected animals. The disease also affects other domestic animals, including swine, sheep, goats and horses. The human disease may be derived from any infected animal. It is impossible to compile accurate statistics of the distribution of the disease in domestic animals, but estimates have been made following tests on cattle in various parts of the United States. According to these estimates, from 6 to 10 per cent of the cattle of this country are excreting Brucella in their milk. A considerably larger percentage of cattle are infected, for not all infected cattle excrete the organism in their milk.

#### SUMMARY

The main facts relative to the incidence of chronic brucellosis may be summarized as follows: 1. Contact with the causal organism is of common occurrence. 2. The severity of infection is known to vary from the acute disease to a form so mild that the subject is unaware of the illness. 3. Clinical diagnosis is extremely difficult, even in severe cases. 4. Brucella infection is known to occur in animals that appear to be healthy. 5. There exists in this country a common malady—the so-called neurasthenia—which in its clinical manifestations cannot always be distinguished from chronic brucellosis.

These facts challenge the right of a physician to make a diagnosis of neurasthenia—a diagnosis regarded as dishonorable by the patient, and also by his family, his employer and his friends—without considering, among other possibilities, the possibility of chronic brucellosis.

## CHORIONEPITHELIOMA

EARLY DIAGNOSIS BY THE QUANTITATIVE DETERMINATION OF ANTERIOR PITUITARY-LIKE PRINCIPLE FROM THE URINE OF PREGNANCY

MICHAEL L. LEVENTHAL, MD

AND

WILLIAM SAPHIR, MD

CHICAGO

While the mechanism and the underlying nature of the increased excretion of the gonadotropic substances during pregnancy are still unsettled problems, the clinical value of the Aschheim-Zondek reaction for the diagnosis of both normal and pathologic pregnancy is well established.<sup>1</sup> Before this biologic test for living chorionic villi was discovered, the diagnosis of early chorionepithelioma was difficult or impossible. Bleeding following labor or molar pregnancy is the usual clinical sign pointing to the possibility of chorionepithelioma, however, the bleeding in early cases may not be associated with tumor formation or diagnostic cuettings. Most cases of chorionepithelioma prior to the utilization of the Aschheim-Zondek test were not diagnosed until a uterine mass was palpable, until a curettage brought forth characteristic tissue, or until metastases in the lungs or vagina appeared. Often a mass was not palpated until metastases had already occurred. Curettage as a diagnostic method not only is uncertain because of the possible location of the tumor at a distance from the endometrium but is dangerous, because the site of a friable growth may be perforated. The use of the Aschheim-Zondek test following mole obviates the necessity of curettage and its attendant dangers and is a diagnostic method by which very early chorionepithelioma may be revealed—before a tumor is palpable or before hemorrhage occurs.

The value of such an accurate test is obvious. The cure of any malignant growth depends greatly on its recognition in an early stage of proliferation, this would hold true especially for chorionepithelioma, in which the degree of malignancy is great and metastases occur early. The detection of metastasis after operation for chorionepithelioma is possible with the Aschheim-Zondek test before clinical signs manifest themselves. If the Aschheim-Zondek test is negative after operation, one may be certain that recurrence or metastasis has not occurred, and therefore follow-up radiation therapy is unnecessary.

Whereas the occurrence of malignant chorionepithelioma is a rarity, hydatidiform mole, which in perhaps 10 per cent of the cases becomes chorionepithelioma, is not an uncommon condition. However, in most patients with hydatidiform mole the diagnosis is not made until the characteristic "grapelike" tumor is expelled. Cases have repeatedly been seen of prolonged bleeding in early pregnancy treated as threatened abortion for weeks before a mole was finally passed, the patient in the meantime developing a marked secondary anemia. In the quantitative hormone test to be described, an additional method becomes available in the diagnostic armamentarium for the recognition of hydatid mole in an early stage. In normal pregnancy the concentration of anterior pituitary-like substance in the urine begins to diminish after the sixth or eighth

week. In hydatidiform mole the concentration increases progressively and rapidly. The high concentration of anterior pituitary-like substance in the urine of patients with hydatidiform mole was demonstrated by Fels,<sup>2</sup> Roessler,<sup>3</sup> Aschheim,<sup>4</sup> Zondek,<sup>1</sup> Philipp, Robert Meyer, Mazer and Edeiken,<sup>5</sup> and Ehrhardt,<sup>6</sup> and these authors have diagnosed mole in doubtful cases by this means. In most instances the quantitative method was a fractional one and involved the provocation of a typical reaction by minute quantities of urine rather than an estimate of the minimum number of mouse units per liter. For example, Ehrhardt in one case obtained a positive reaction with  $\frac{1}{520}$  cc of urine, and in another with  $\frac{1}{260}$  cc.

The quantitative estimations of gonadotropic factor in the urine in chorionepithelioma have been reported by Fels, Robert Meyer and Ehrhardt. Fels, in a case of testicular chorionepithelioma, demonstrated the presence of 33,000 mouse units per liter of urine, Robert Meyer 70,000 mouse units per liter in a case of renal chorionepithelioma, and Ehrhardt 100,000 mouse units per liter in a case of primary uterine chorionepithelioma.

It is our purpose in this paper to describe a simple method for the quantitative determination of anterior pituitary-like factor in the urine, to stress the value of this test in the early recognition and differential diagnosis of chorionepithelioma (and hydatidiform mole), and to record an unusually early chorionepithelioma.

## TECHNIC

While the Friedman rabbit test seems now to be the method of choice in the diagnosis of pregnancy, the original mouse or rat test is distinctly preferable for the exact quantitative determination of anterior pituitary-like substance in the urine. The original Aschheim-Zondek method was therefore used, with slight modification, as follows. The patient's morning urine specimen is diluted with physiologic solution of sodium chloride in fractional concentrations such as 1/10, 1/50, 1/100 and 1/1,000. From three to five infantile white female mice, weighing from 6 to 8 Gm, are injected with a total of 3 cc of each of the dilutions within 100 hours. The animals are thereafter examined for the presence of vaginal cornification and ovarian stimulation, such as folliculation, hemorrhage and luteinization as stated in a previous communication.<sup>7</sup> On the assumption that a positive reaction would not be obtained with any of the dilutions but only with the undiluted native urine specimen, this would indicate that 3 cc of urine contains at least 1 mouse unit, or 1 liter of urine a minimum of 333 mouse units. Accordingly, a positive reaction obtained with a 1/10 dilution would indicate a minimum excretion of 3,330 mouse units per liter, a positive reaction with 1/100 dilution, an excretion of 33,300 mouse units, and so on. It has been established that, in terms of mouse units, the excretion of the gonadotropic substance amounts to from 5 to 10 mouse units per liter of urine in both normal man and woman. This amount rises sharply to from 5,000 to 20,000 mouse units in normal pregnancy, and any amount above 20,000 mouse units is indicative of the presence of a pathologic pregnancy such as hydatid mole or chorionepithelioma.

## REPORT OF CASE

Mrs. S. S., aged 36, had her last regular menstrual period, July 10, 1933. On August 25, she began to bleed profusely with the passage of clots. The uterus was enlarged, soft and globular, and a tentative diagnosis of pregnancy with threatened abortion was made. The bleeding stopped in eight days and the patient was well until October 30, when, following a profuse hemorrhage, a large hydatidiform mole was passed. Under ethylene anesthesia the cervix was found to be completely dilated, and digital exploration of the uterine cavity revealed some loose hydatid tissue, however, no masses or evidence of muscular invasion were discovered. The endometrium was sharply curetted. The patient left the hospital in five days feeling well but began to bleed again, December 9, the bleeding lasting three days and simulating a menstrual flow. December 22, bleeding again occurred and this time was associated with severe pain in the left lower quadrant.

Bimanual examination at this time revealed an enlarged soft uterus, and the left ovary was cystic and approximately the size of a lemon. An Aschheim-Zondek test, December 20, gave a very strongly positive reaction (reaction III). Because of recurrent bleeding and because of the extremely positive Aschheim-Zondek reaction it was decided to curet again and look for evidence of recurrent mole or chorionepithelioma. December 23 a diagnostic curettage was performed and only tissue resembling normal endometrium was obtained. There was no evidence of hydatid mole or chorionepithelioma. The uterus was only slightly enlarged and the left cystic ovary was accidentally ruptured during the bimanual examination.

The microscopic report of the tissue removed was as follows: "Degenerated placental tissue with moderate acute and chronic inflammatory changes. Indistinct outlines of hydatidiform mole. No evidence of malignancy." Jan. 6, 1934, the pelvic status was normal. An Aschheim-Zondek test, January 8, was strongly positive with 10 cc of urine. January 26 there began a normal menstrual period. Bleeding occurred again on February 13 but the uterus and adnexa showed no abnormalities on bimanual examination. February 22 the Aschheim-Zondek test was strongly positive with 10 cc of urine. March 1, four months after the passage of the mole, 3 cc of urine gave a strongly positive Aschheim-Zondek test with, quantitatively, 333,000 mouse units per liter of urine. The pelvic status on bimanual examination was entirely normal at this time. With this concentration of gonadotropic substance we strongly advised panhysterectomy. A roentgenogram of the chest showed no pulmonary lesions.

March 8, under ethylene anesthesia the abdomen was opened through a midline incision from the umbilicus to the symphysis. The uterus and tubes appeared normal in all respects, and the ovaries were only slightly enlarged and somewhat cystic. In spite of the normal appearance of the pelvic viscera, the high quantitative gonadotropic contents of the urine impelled us to continue with our original plan and a panhysterectomy and bilateral salpingo-oophorectomy were performed. The patient made an uneventful recovery and was discharged from the hospital twenty days after operation. March 17, nine days after operation, the Aschheim-Zondek test was positive with 10 cc of urine. March 27, 10 cc of urine gave a questionably positive test (reaction I) and 5 cc of urine gave a negative test. Quantitative estimation of anterior pituitary-like substance in this specimen revealed 15,000 mouse units per liter, a very marked diminution in amount under the previous 333,000 mouse units and indicating a disappearance of the effect of the pathologic lesion. April 20 the Aschheim-Zondek test was completely negative indicating no viable chorionic tissue (no metastases).

## PATHOLOGIC REPORT (DR. OTTO SAPHIR)

The specimen consisted of a cervix, uterus, both tubes and both ovaries. The cervix and uterus together measured 8.5 cm in length. The cervix was slightly dilated, the mucosa was in some portions distinctly granular in appearance but otherwise showed no gross changes. The uterine cavity appeared normal in size and the lower third portion showed a normal mucosa. The mucosa in the upper two thirds was distinctly elevated, grayish white and very soft and friable in consistency. There were distinct minute areas of hemorrhage present in

this region. Occasionally, minute cystic structures were seen which were not well outlined and which might have signified an edema in this region. Minute cysts were also seen within the right upper horn of the uterus and within the myometrium. The left lateral wall of the uterus showed a small tumor measuring about 5 mm in diameter which had the characteristics of a myofibroma. The myometrium in general was yellowish pink but showed no changes. Within the wall of the uterus, at a distance of about 6 mm from the endometrium and situated in the posterior wall close to the left horn, there was a tumor which measured about 1 cm in diameter, was roughly round, well defined and of a reddish yellow color (fig. 1). Its center was necrotic and contained much clotted blood. The peripheral portions of the tumor were very soft and contained much necrotic material and many hemorrhagic zones. The appearance of the tumor might well have been compared with that of a hemorrhagic corpus luteum. There was no extension of the tumor into the endometrium. As a matter of fact, evidence of it was not seen when the uterus was opened but was revealed only after multiple sections were made through the myometrium. The tubes showed no gross abnormalities. The right ovary was slightly larger than normal. There was a hemorrhagic cyst, 10 by 15 mm in diameter, the wall of which was smooth and gray. One hemorrhagic corpus luteum cyst was seen which measured about

Fig. 1—Early chorionepithelioma. Note tumor in the myometrium.

7 mm in diameter. The left ovary also revealed one corpus luteum cyst measuring about 6 mm in diameter, but no other changes could be recognized.

Microscopically, section of the endometrium revealed a diffuse infiltration of lymphocytes, endothelial cells and a few polymorphonuclear leukocytes. Occasionally, accumulations of plasma cells were seen throughout. There was a distinct increase of the connective tissue. The glandular structures were clearly recognizable. Some of the tubuli contained red cells and a few polymorphonuclear leukocytes. The myometrium throughout showed foci of lymphocytes surrounding small blood vessels. There was no evidence of decidua or villi.

Sections of the tumor, described grossly, showed the following changes. The bulk of the tumor showed only large areas of necrosis with many red cells and much fibrin throughout, but no clearly outlined nuclei could be noted (fig. 2). Only occasionally in the midst of the necrotic material, outlines of pink-stained structures were present which resembled chorionic villi. In the vicinity of the villi a few cells showed a light stained cytoplasm and an eccentrically situated vesicular nucleus. The more peripheral portions of the tumor showed a variety of changes. There were many villi which varied in size; some of them were replaced by a hyalin-like material while others were necrotic. Between the villi there were many large cells with a light pink-stained, clear or foamy cytoplasm. In some fields these cells were filled with a golden brown pigment (apparently blood pigment). Often the foamy cells

surrounded the villi. Also, typical syncytial giant cell masses were seen, and giant cells showing three or four hyperchromatic nuclei, which were distributed diffusely throughout the cytoplasm (fig 3). In addition, there were many lymphocytes throughout the sections, with foci of a reddish brown (blood) pigment. Typical Langhan's cells were not found.

#### PATHOLOGIC CHANGES AND CLASSIFICATION OF TUMOR

Within the myometrium, a tumor was found which consisted largely of villi, syncytial giant cells, much necrosis, fibrin and evidence of considerable hemor-

Fig 2—Section of tumor under low power, showing necrotic villi

rhage. The question arose as to whether these anatomic changes indicated a chorionepithelioma, a syncytioma, or a so-called syncytial hyperplasia (Ewing). Whereas elements of placenta were surely present in the myometrium in relatively large masses, where under normal conditions they should not be present, morphologically the individual structures showed no evidence of a malignant condition, there were no mitotic figures, there was no invasion of blood vessels, the variation in size, shape and staining quality of the individual cells was not conspicuous. Evidence of regressive changes predominated. There was much necrosis, hemorrhage, and an abundance of phagocytic cells, some of which were laden with hemosiderin. There are instances of chorionepithelioma described, however, which were characterized by such regressive changes (supposedly due to a lytic toxin).

The presence of lutein cysts in the ovaries in our case may speak for chorionepithelioma. From the morphologic point of view, because of the absence of histologic evidence of a malignant condition, this tumor could not be called "typical chorionepithelioma." To differentiate the typical chorionepithelioma (choriocarcinoma) with its well known morphologic picture from other forms of tumor somewhat resembling the former, Marchand ascribed the term "atypical chorionepithelioma" to the latter. These are the cases he believed, in which recovery was reported after curettage.

Syncytial hyperplasia (syncytial endometritis) is a type of lesion that has evoked discussion as to whether it is a new growth or an exaggeration of a normal reaction to pregnancy. If one regards this as a new growth, it also belongs to the group classified as "atypical chorionepithelioma" by Marchand.<sup>8</sup> Geist,<sup>9</sup> however,

concluded that this is really not a neoplasm in the true sense of the word and created the term "syncytial hyperplasia." In this condition, syncytial invasion of the muscularis of the uterus constitutes the chief pathologic change in the entire process. In our case, while the anatomic description might well correspond to "syncytial hyperplasia," the fact that the lesion was found at a distance from the endometrium and grossly appeared as a tumor makes it unlikely that it should be designated as syncytial hyperplasia.

Syncytioma is a definite tumor made up of groups or islets of syncytial cells, and often giant cells, which form the smaller part of the tumor. The greater part is made up of blood clot, degenerating and necrotic tissue, fibrin and leukocytes, the function of the latter being phagocytic. This process, regressive in character, represents a transition from the syncytial hyperplasia on the one hand to advanced chorionepithelioma on the other. It is the first real step in the nature of a true neoplasm (Geist). Langhan's cells are absent in this tumor. Marchand includes this type of tumor under the broad term "atypical chorionepithelioma." Our case fits very well the description of Geist, and, with his classification, this tumor should be designated as syncytioma. However, if one should follow Marchand's classification, this would be an atypical chorionepithelioma.

#### COMMENT

This case illustrates the importance of determining quantitatively the amount of anterior pituitary-like substance in the urine following the expulsion of a hydatidiform mole. Although histologically our tumor was not the most malignant type of chorionepithelioma (choriocarcinoma), still the high gonadotropic concentration as a biologic indicator points to the potentiality of profound malignant change. This is important because the histologic picture is not always a true prog-

Fig 3—Section of tumor under high power showing degenerated villi and syncytial giant cells

nostic index in chorionepithelioma. This fact was well demonstrated in the unusual case recently reported by Lackner and Leventhal,<sup>10</sup> in which, microscopically, a typical choriocarcinoma was found, and, in spite of both pulmonary and vaginal metastases, cure (the patient is now well after eight years) followed hysterectomy and high voltage roentgen irradiation. It will be interesting, in the future, to note whether the amount

8 Marchand F. *Ztschr f Geburtsh u Gynäk* 39: 173 1898  
9 Geist S H. *Surg Gynec & Obst* 32: 427 (May) 1921

10 Lackner J E and Leventhal M L. *Chorionepithelioma of the Uterus* J A M A 98: 1136 (April 2) 1932

of anterior pituitary-like principle bears any relation to the histologic classification of the choriomas (as set forth by Ewing)

The performance of a very radical operation entirely on the basis of a laboratory finding, and in the absence of any palpable or visible pathologic change was justified by the discovery of a potentially malignant tumor in a very early stage of its proliferation. The disappearance of a positive Aschheim-Zondek test following operation is a true indication of the absence of live chorionic villi (recurrence or metastasis). Therefore the use of postoperative radiation therapy is unnecessary in the presence of a negative test. This would obviate the deleterious effects of irradiation in cases in which it is not needed.

#### SUMMARY AND CONCLUSIONS

1 The quantitative determination of the gonadotropic substance in the urine is an important biologic test in the early diagnosis of chorionepithelioma.

2 Following the expulsion of a hydatidiform mole, this quantitative test forms a prognostic index for chorionepithelioma formation.

3 In the absence of clinical manifestations, an amount of gonadotropic substance in the urine in excess of 20,000 mouse units per liter indicates an early chorionepithelioma.

4 A case of early chorionepithelioma was diagnosed and an operation was performed solely on the basis of the laboratory finding of 333,000 mouse units of gonadotropic substance per liter of urine in a patient who had expelled a hydatid mole four and one-half months previously.

5 Recurrence of chorionepithelioma or metastases may be discovered by the Aschheim-Zondek reaction, and this should determine the use of radiation therapy.

## Clinical Notes, Suggestions and New Instruments

### ABDOMINOSCROTAL HYDROCELE

A BRIEF DISCUSSION AND REPORT OF A CASE

CHARLES S. ROLLER, M.D. CALUSA, CALIF.

There probably have been a good many abdominoscrotal hydroceles operated on, but very few cases are recorded in the literature. The condition is sufficiently uncommon to be reported, if for no other reason than in an effort to avoid errors in opening the abdomen for removal of these tumors, which are always extraperitoneal. Hydrocele of the cord and of the tunica vaginalis combined seems to me to be without much question, the etiology. A hydrocele of the inguinal cord with a competent external inguinal ring could develop in no other location than within the inguinal canal until its size made it imperative that it expand elsewhere. The normal inguinal canal, to an expansive force within the canal itself is weakest posteriorly. A developing tumor within the canal could most easily extend posteriorly by separating the peritoneum and preperitoneal tissues from the internal surface of the transversalis muscle. Anteriorly the very tough fascia of the external oblique muscle offers resistance, and medially, laterally and superiorly the conjoined tendon, the inguinal ligament and the arching or shelving fibers of the internal oblique and transversalis muscles are all firm barriers. Hence the developing hydrocele must go posterior to these structures, to spread out unhampered in all directions between them and the peritoneum. This is exactly the position that the abdominal portion of the tumor is found to occupy. When large the hydrocele displaces and may be adherent to the bladder, may partially fill the

pelvis and may intimately approach the great pelvic vessels, it may also displace the sigmoid colon well medially if the lesion is on the left side. The hydrocele may reach a great size and cause a huge visible tumor in the lower part of the abdomen. Hydroceles probably are all congenital. Perhaps a more exact name would be inguinoscrotal hydrocele.

The only symptoms are usually an abdominal and scrotal painless swelling. Catheterization to rule out residual urine, a cystogram, barium enemas with fluoroscopy and films of the large bowel should easily make the diagnosis and exclude an intra-abdominal tumor. The abdominal portion is usually not movable, is rather tense and distinctly cystic, and is painless.

Curtis<sup>1</sup> reported a case in a youth, aged 19 years, with a history of trauma as the etiology. The tumor was the size of a grapefruit and seemed to be part of a cystic swelling of the scrotum on the same side. Operation revealed an abdominoscrotal hydrocele, which was removed together with the testicle and a portion of the cord. Recovery followed. Herrmann<sup>2</sup> reported a similar case in a man aged 26, with a much larger abdominoscrotal hydrocele (containing 3 liters of fluid) and

Abdominoscrotal hydrocele sac. Appearance after removal and withdrawal of fluid for measurement. (It contained 3,400 cc.) The larger sac is the abdominal portion. The neck connecting the two tumors is well shown. The combined length is a little over 30 cm. (12 inches).

with a fluid connection between the scrotal and abdominal portions demonstrable by fluid wave before operation. The tumor and testicle were removed, followed by recovery of the patient. Lakhoti<sup>3</sup> reports a case of an Indian, aged 40, who was cured by operation without removal of the testicle. The tumor was rather small. Richards<sup>4</sup> in 1908 reported a case in an Egyptian and cited thirty-one other cases. Bickle<sup>5</sup> reported a case in 1919 and possibly was the first to state that abdominoscrotal hydrocele was a better term than bilocular hydrocele, with which I agree. Coleman<sup>6</sup> reported a case in an Egyptian with a huge tumor, the sac containing 27 pints (15 liters) of fluid.

## REPORT OF CASE

**History**—G R., a white man, aged 26, an American, who was referred to me, complained of swelling in the left scrotum, swelling in the abdomen and loss of 15 pounds (68 Kg) in the last two months.

Eighteen months before, the patient noted a swelling in the left scrotum, which gradually enlarged to the size of a grapefruit and was aspirated six months later. The swelling soon returned and became larger than before aspiration. About seven months before admission he noted, for the first time, that the lower left portion of the abdomen was swollen and hard. Both tumors had greatly increased in size since then. The patient had never had any pain but came for relief of the huge scrotal and abdominal swelling, which gave him a constant sense of weight in the scrotum and bothered him when working. He believed that his weight loss was due to a severe cold, which he had contracted two months previously and from which he had just recovered.

The past and family history are not important.

**Physical Examination**—Inspection revealed a huge bulging tumor occupying the entire left lower part of the abdomen, extending to the left wall beyond the midline and upward to 3 inches above the umbilicus. This tumor was continuous by a neck of tissue, about 1 inch in diameter and  $1\frac{1}{2}$  inches long with a swelling in the left scrotum of about 4 by  $5\frac{1}{2}$  inches. Both tumors were tense, cystic and painless, and contained fluid. The scrotal hydrocele sac was thick walled and transmitted light poorly. The testicle was felt with difficulty, posterior to the scrotal swelling, and seemed hard and enlarged and flattened. There was a moderate adenopathy of the left inguinal region. A definite tubular patent connection of fluid existed between the scrotal and abdominal tumors, as demonstrated by a very positive fluid wave transmitted between them. The neck connecting the two was cystic and was compressible between the fingers. There were no other abdominal changes. On rectal examination one could just detect the cystic tumor anteriorly and to the left.

The blood and urine were essentially normal. The Wassermann reaction was negative, the catheter revealed no residual urine. A cystogram revealed a normal bladder displaced about 3 cm to the right. Fluoroscopy during a barium enema revealed the mass to be displacing the sigmoid markedly to the right, but the bowel was movable and otherwise normal. Fluoroscopy and films demonstrated the mass to lie anterior to the sigmoid. A film of the chest shows evidence of what probably had been a mild pulmonary tuberculosis some time in the past but with no evidence of activity at present.

The preoperative diagnosis was (1) huge hydrocele of the cord and tunica vaginalis, (2) possibly a malignant tumor of the testicle?

**Operation**—Under low spinal anesthesia (120 mg of procaine hydrochloride) an incision was made from the left external inguinal ring to 7 cm above and 4 cm internal to the left anterior superior spine of the ileum. When the fascia of the external oblique was opened and the incision was continued up for several centimeters into the belly of the muscle, it was seen that the huge cystic tumor was beneath the internal oblique and transversalis muscles, pushing the peritoneum aside. The abdominal mass was connected by a patent neck to the hydrocele of the scrotum. The scrotal portion of the tumor was at once shelled out along with the contained testicle. By using this as a very convenient method of traction, the abdominal mass was slowly separated, by blunt dissection, from the lateral pelvic wall, transversalis muscle, peritoneum, bladder and pelvic vessels. It was removed intact. Some care was necessary to prevent injury to these structures. Very little bleeding occurred. The spermatic artery and a few small vessels required ligation. The peritoneal cavity was not opened. The huge defect was obliterated easily by approximation sutures of a plain catgut. The transversalis and internal oblique muscles were approximated with interrupted sutures of no. 2 chromic catgut, and the repair was carried on down to the pubic spine in the same manner, the conjoint tendon and the shelving edge of the transversalis and internal oblique being sutured to the inguinal ligament and the inguinal canal being thus completely obliterated. The incision in the external oblique muscle and fascia was repaired in the same manner down to

the pubic spine, thus making a very firm repair of the huge potential hernia. A small drain had previously been inserted down lateral to the bladder and in the scrotum. The wound was then closed.

The patient made an excellent recovery aside from a mild attack of bronchial pneumonia suffered the first few days after operation. It will be remembered that only spinal anesthesia was given. The drains were removed on the third day and the skin sutures on the tenth day, and the wound healed by first intention. The patient was seen five weeks later in the outpatient department. He had gained 5 pounds (23 Kg), the wound was firm, the left scrotum had shrunk to less than normal size and the abdomen was flat and soft. Six months later he had gained 26 pounds (118 Kg) and was in excellent health.

The combined content of the abdominal and scrotal hydroceles measured about 3,400 cc of clear light yellow fluid. Cultures remained sterile. A centrifugated specimen revealed detritus and a few degenerated epithelial cells. The testicle was small, colorless and flattened and surrounded by a thick mass of fibrous tissue, which appeared to have grown from the wall of the sac and capsule of the hydrocele. No malignant tissue was found.

AN UNUSUAL CARPAL FRACTURE DISLOCATION  
REPORT OF CASE

GEORGE L. APFELBACH, M.D.

Professor of Surgery, Cook County Post Graduate School, Attending Surgeon, Cook County Hospital

AND

CARLO S. SCUDERI, M.D.

Associate Attending Surgeon, Cook County Hospital, Instructor of Surgery, University of Illinois College of Medicine

CHICAGO

In reviewing the literature of the past ten years on carpal injuries we have been unable to find a reference to any case in which a fragment of the navicular bone and the entire lunate

Fig. 1—The distal fragment of the navicular bone and the multangular major are seen articulating with the radial facet. The dislocated bones are seen rotated and pushed well into the forearm.

were dislocated into the volar surface of the lower third of the forearm.

In order to permit such a displacement between the flexor tendons, the annular ligament of the wrist must have been torn.

This case is being reported because the bones were dislocated so far from their normal position and because the end result of carpalectomy was excellent.

From the Fracture Service of the Cook County Hospital

W L, a Negro girl, aged 17 years, admitted to the Cook County Hospital, March 12, 1933, was in a condition of serious shock. While washing windows, she fell out of a fourth story window, landing in a cement courtyard.

The injuries are enumerated as follows:

- 1 Basal skull fracture with bilateral ecchymosis of the orbits and bleeding from the nose, associated with deep coma
- 2 Depressed fracture of the right maxilla
- 3 Comminuted fracture of the left mandibular angle
- 4 Fractured superior and inferior rami of the left pubic bone, in good position

Fig 2—Sectional decalcified bones. The articular surfaces of the bone are practically intact. The medullary portions of the bones show moderate fibrosis in a few areas. The bony trabeculations are all intact. This section shows the bone after having been dislocated into the forearm for approximately three months.

- 5 Fracture of the internal malleolus of the right ankle, in good position
- 6 Fracture dislocation of the proximal two thirds of the carpal navicular bone and lunate into the volar surface of the forearm

After two months of hospitalization the patient was able to be up and about. May 3, she was discharged from the hospital, temporarily, with a low grade osteomyelitis of the jaw and the dislocated carpal bones. She was instructed to return biweekly for observation. A posterior molded splint was used for one month only, in the treatment of the carpal injury.

Fig 3—The amount of flexion and extension of the wrist nine months after the injury and six months after the carpectomy. All motion of the wrist was painless at this time.

June 8 the carpal bones were removed under local anesthesia, because of progressive causalgia over the distribution of the median nerve and increasing paresis over the median distribution of the intrinsic muscles of the hand.

At operation the bones were found between the tendons of the flexor digitorum sublimis and the flexor digitorum profundus with much scar tissue firmly fixing the bones to the epineurium of the median nerve. By sharp dissection the bones

were liberated. The hand made an excellent recovery. When last seen, in January 1934, photographs were taken showing the limit of function, which was painless. The end result was very gratifying to both the patient and ourselves.

## Special Article

### THE DIONNE QUINTUPLETS

ALLAN ROY DAFOE, M.D. (UNIVERSITY OF TORONTO)  
CALLANDER, ONTARIO

The arrival into the world of one baby is generally a matter of some local interest, but the arrival of five babies is so unusual that the interest spreads far afield and the event becomes worthy of recording in medical history.

During the last five hundred years there have been thirty-two authentic cases of quintuplets recorded. Of these, only one group of all five lived about an hour, and of another group, only one of the five lived for

Front view of the Dionne home. The nursery window is to the left of the door.

fifty days. To these records I wish to add a short history of the birth and early care of the Dionne quintuplets. At the time of writing (July 28, 1934) the five babies are thriving and healthy at the age of 2 months and are gaining steadily in weight.

My practice is situated in a French-Canadian settlement, with my home in Callander, a small village on the East shore of Lake Nipissing, two hundred miles north of Lake Ontario. In this area there are about 3,500 people. My practice covers about four hundred square miles. The French-Canadians first came here about half a century ago, following lumbering activities of that time. Their families followed. They took up land and cleared their farms. This country is studded with lakes with many beautiful camping spots but the land is rocky, with fertile patches. There is lots of hard work necessary to live and actual money is noted for its scarcity. In the winter time the men get some extra work in lumber camps, but in the summer they make their living on their farms, by road work or in the sawmills. For the last two years a large percentage of the people have been on relief.

The first incubator was brought from Chicago on the third day, and the three smallest babies were placed in it, the other two remaining in the basket. Within a week, another incubator arrived and then finally there was one for each baby. The temperature was kept between 87 and 90 at first. As time went on the temperature was gradually lowered and maintained at 84. The moisture was kept up by sponges within the incubators soaked in hot water. As the humidity of incubators is so important, I was able to procure humidity recording instru-

Marie Dionne aged 2 months weight 3 pounds 5 ounces

ments, which were hooked on the inside of each incubator. These were kept between 50 and 55 degrees. The incubator that arrived first was made with a hollow frame, a glass-hinged top fitted with a thermometer and a sponge holder. It was heated by hot water in a copper tank. The other incubators were similar in construction but heated by "little pigs" placed in several small compartments with movable doors.

The first week was a nightmare with the frequent alarms, and innumerable trips sandwiched between my other calls. The babies needed constant supervision and frequent stimulation to arouse them out of their attacks of cyanosis. On the fifth day the three smaller ones were markedly distended and looked worse than usual. There had been no bowel movement for two days. I gave them all a saline enema with a fine catheter and a hypodermic syringe and obtained quite a few yellowish black pellets. They seemed to pick up after this and took their food better. Within a week, cylinders of 95 per cent oxygen and 5 per cent carbon dioxide were obtained, with a reducing valve and an ordinary inhalator. This gas then replaced all other methods of stimulation and the rum rations were seldom issued (Yandell Henderson of Yale was largely responsible for the introduction of this method of treatment for asphyxia of the new-born.) It certainly was most valuable with these babies. Inhalations were given for a few minutes before each feeding in the early stages and with every attack of dyspnea and cyanosis. There was a decided maintained improvement following the use of the gas mixture. All the babies began to show a slight but perceptible gain in weight. Even yet the smaller babies frequently become cyanotic, and we are still using the same gas mixture daily.

*Second Week*—Supplies and equipment were pouring in and we now had an opportunity to organize our forces and lay out a campaign. The doors and windows were all screened to shut

out flies and mosquitoes. The babies' room was carefully gone over and all possible measure of aseptic technic introduced, including gowns and masks. The nurses through a women's organization of North Bay made special little Red Riding Hood dresses without sleeves, absorbent cotton gauze jackets, rectal pads, and fashioned the diapers to suit their small bodies. Each baby even had its own pile of mouth wipes. The rest of the children of the family were moved to other quarters, as two or three of them had developed bronchitis. The nurses have been intelligent, vigilant and most faithful, and a great deal of credit should go to them for the survival of the babies. Every physician knows the value of good nursing in the care of premature infants, and in this case the results are the reflection of the painstaking service carried out by the nurses.

I wish to acknowledge the valuable advice concerning modern methods and treatment given me by my brother, Dr. W. A. Dafoe of the Department of Obstetrics and Gynaecology, University of Toronto. From the first week I have been in touch with him personally and by telephone. On request he has visited the mother and children twice and, in addition to giving me medical help, he has aided me in dealing with promoters, reporters and the general public.

*Subsequent History*—The babies have had their "ups and downs" since, but they are progressing favorably in health and gaining steadily in weight. They were at first fed every two hours. This was advanced to two and a half hours and then to three hours. The feedings are given to them in their incubators. They are moved out as little as possible. Once a day they are given olive oil baths. The babies appear to resemble one another considerably, and their eyes are beginning to follow movements near them. Little Marie has a hemangioma over the right thigh, which is growing. It will be treated with radium. The mother developed a phlebitis of the long saphenous vein in the right leg on the eleventh day. She had been

Composite weights of the Dionne quintuplets

sitting up for two days. The patient was put back to bed until her temperature was normal for two weeks. She is quite well now.

#### COMMENT

The publicity in connection with this case has been a serious problem and has caused me considerable trouble and worry. There has been no let-up from the moment of the uncle's naive enquiry to the North Bay paper as to how much it would cost to insert a birth notice for five babies born at one time. At first I

resented what I felt was an intrusion into my private and professional affairs. Then I came to realize that I had no right to object to what had become a matter of continent-wide interest. I have been increasingly grateful to the newspapers for the invaluable supplies and equipment which from the beginning came as a result of this publicity. As for myself, I have had an opportunity which I could never otherwise have enjoyed of meeting by letter, or in person, some of the outstanding men of our profession in Canada and the United States.

It would be impossible to thank the many people "in" and "out" of the profession whose help has enabled us to keep the children alive. We have indeed appreciated all that has been done. I should like to mention particularly the work of the Canadian Red Cross Association, which from the first has given cordial cooperation and has taken over a good share of responsibility for the welfare of the babies. Above all, we are grateful to the Ontario government, which has supplied the whole family with food and clothing, has repaired the road, and has definitely supported our efforts against public display. With such cooperation we hope the babies will continue to thrive and will be a credit to their family and to their country.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
H. A. CARTER

### FOREGGER INFANT RESUSCITATION OUTFIT ACCEPTABLE

The Foregger Infant Resuscitation Outfit is manufactured by the Foregger Company, Inc. New York City. It is an apparatus which permits the use of two standard mixtures of carbon dioxide and oxygen alternately, viz. 30:70 and 5:95. One unit was examined in a clinic acceptable to the Council. The report is as follows:

Observations were made on twelve newly born infants showing varying degrees of asphyxia. Treatment for asphyxia was instituted immediately following delivery. The menstrual age was estimated at 40 weeks in ten cases, 38 weeks in one case and 28 weeks in another.

The methods of delivery varied. Three babies were delivered spontaneously, two by laparotrachelotomy, three by breech extraction, two by difficult high forceps operations, and the remaining two by low forceps operations.

Fetal distress was observed in four cases prior to delivery, which was evidenced by alteration of fetal heart tones and the presence of meconium in the amniotic fluid.

#### DESCRIPTION OF FOREGGER OUTFIT

The apparatus consists of a sturdy machine which permits the administration alternately of two standard mixtures of oxygen and carbon dioxide. There is an accurate metric gage on the apparatus which permits the control of the amount of gas used, thereby making the operation of this apparatus more economical. The inhalation mask with its attached rubber breathing bag, makes the operation of tracheal insufflation more simple. The safety valve eliminates the danger of too great gas pressure in carrying out the foregoing procedure.

#### CRITERIA OF ASPHYXIA

The degree of asphyxia varied. The criteria used in our observations included apnea, cyanosis or pallor, flaccidity and the absence of or a diminished pharyngeal reflex.

#### TECHNIC OF RESUSCITATION

The asphyxiated infants were handled as little as possible. The nasopharynx being cleansed of mucus by either postural drainage, the use of the gloved finger or, when necessary, the

use of the tracheal catheter. The body heat was conserved as much as possible by the covering of the infant and by the use of hot water bottles. If the period of apnea was long, a mixture of carbon dioxide and oxygen was used. By our previous work, the amounts of carbon dioxide and oxygen found to be the most useful were those of 30:70 and 5:95 ratios. The asphyxiated infants were given the 30 per cent carbon dioxide mixture first and gentle rhythmic compression of the chest was used until spontaneous respiration was established. This mixture was then discontinued and the 5 per cent carbon dioxide and 95 per cent oxygen mixture administered.

It is to be understood that tanks containing any percentage of carbon dioxide and oxygen can be attached to this apparatus. One could attach a tank containing the desired percentage of carbon dioxide and oxygen and another containing pure oxygen should the user so desire.

#### ETIOLOGY OF ASPHYXIA

The etiology of asphyxia was obscure in three cases. Trauma was cited in five cases and aspiration in eight cases. A combination of the latter two contributory etiologic factors were blamed in four cases. Seven of the mothers had received narcotics during the first stage of labor. One mother had received only pentobarbital for analgesia. Narcotization was ascribed as the etiologic factor in four cases. A diagnosis of fetal narcosis was made from the history, pupillary reflexes, and the response to ventilation of the lungs with oxygen and carbon dioxide. In fact, the latter sign has proved to be almost pathognomonic.

#### ASPIRATION

Aspiration of mucus in varying amounts was listed as the contributory factor in eight cases. The measures already mentioned were taken to remove this obstruction.

#### TRAUMA

Trauma occurred to a mild degree in four cases. In one case, severe trauma was present. A difficult breech extraction of an 8 pound 5 ounce (3,770 Gm.) male infant was done through a contracted pelvis. The infant suffered from a depressed skull fracture and a complete fracture of the right clavicle. Nevertheless, the oligo-apnea was relieved promptly, following the removal of aspirated mucus from the trachea and the administration of oxygen and carbon dioxide. Our observations lead us to believe that trauma has a definite relationship in the association of narcotization with asphyxia.

Foregger Infant Resuscitation Apparatus

#### CIRCULATION

No definite observation was made of the fetal circulation following delivery in four cases, but heart action was described as normal in eight cases.

#### NATURE OF RESPIRATION BEFORE TREATMENT

The nature of fetal respirations at birth were noted as follows: none, three; gasps, eight; poor, one.

#### PHARYNGEAL REFLEX

The character of the pharyngeal or gluteal reflex was found to be our best index as to the degree of asphyxia present. There was no notation of this observation in one case. It was described as absent in three cases, fair in one case, and good in seven cases.

#### TIME RELATION TO TREATMENT

Treatment was given immediately following delivery in all cases of apnea or oligo-apnea. Gasps had occurred before treatment in eight cases, but in several of these respiratory efforts ceased until further stimulation by gaseous resuscitation was used. The average interval between delivery and beginning treatment was from three to five minutes.

#### RESULTS

Treatment was usually continued from two to ten minutes. In one case intermittent treatment was given until postnatal death occurred several hours later. The condition of the infants

was described as good on leaving the delivery room in nine cases, fair in two cases and poor in one case. There were two postnatal deaths. One was a previable fetus, which was included in the series only to demonstrate how respiratory efforts could be repeatedly stimulated over a period of time by the use of gaseous resuscitation procedures. The second postnatal death was that of a 2,765 Gm male infant delivered by cesarean section from a mother suffering from severe pre-eclamptic toxemia.

It should be remembered that the stronger percentages of carbon dioxide and oxygen or mixture with oxygen should be utilized for only a very brief period of time, following which the infant should be given a mixture containing either a very low percentage of carbon dioxide or pure oxygen. This should be discontinued promptly as soon as circulation is well established and the infant's oxygenation is good.

The Foregger Infant Resuscitation Outfit is included in the Council's list of accepted devices for physical therapy.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING SPECIAL REPORT WHICH HAS BEEN SUBMITTED TO THE FOOD AND DRUG ADMINISTRATION OF THE U. S. DEPARTMENT OF AGRICULTURE, THE NATIONAL INSTITUTE OF HEALTH, THE NATIONAL FORMULARY COMMITTEE AND THE COMBINED CONTACT COMMITTEE OF THE AMERICAN DRUG MANUFACTURERS' ASSOCIATION AND THE AMERICAN PHARMACEUTICAL MANUFACTURERS' ASSOCIATION. THESE ORGANIZATIONS HAVE GIVEN PERMISSION TO QUOTE FROM CERTAIN OF THEIR PUBLICATIONS.

PAUL NICHOLAS LEECH, Secretary

### REPORT ON STERILITY OF AMPULE PREPARATIONS

An article by Gershenfeld in the *American Journal of Pharmacy* (105:155, 1933) raised anew the question of the sterility of ampule preparations of medicinal products used for parenteral injection. In the discussion of this question before the Council it became apparent that neither the Council nor the National Institute of Health was in a position to take up a bacteriologic survey of these products or to establish an extensive system of control. It was agreed that, although a bacteriologic survey could not be undertaken now, it would be advantageous for the Council and other interested organizations to have a report on the procedures and tests used by manufacturers to determine whether or not the contents of their ampule preparations are sterile.

The chief of the Food and Drug Administration of the U. S. Department of Agriculture, under date of Aug. 2, 1933, informed the Council that an investigation of the sterility of ampule preparations carried out by the administration in 1925 and 1926 showed that these preparations were sterile. This official stated that following Gershenfeld's article a resurvey was started of these ampule preparations. He anticipated that this survey would take some time because of the large number of ampule products offered for sale on the American market. Since the need for control has been recognized, the Council noted with satisfaction this significant statement in the letter from the Chief of the Food and Drug Administration.

The article in your report raises the question as to whether or not some agency of the United States Government should maintain a check over these articles. Their label claims bring them under the control of this Administration and it is our purpose to keep as complete a check as possible on such preparations.

After the action of the Council it was discovered that at least two other organizations are interested in the question of the sterility of ampule preparations. These are (1) the National Formulary Committee, whose Bulletin for Sept. 14, 1933, pp. 1163-1165, contains a discussion of the question with proposed regulations, (2) the Subcommittee on Standard Methods for Testing Ampoule Solutions for Sterility of the Combined Pharmaceutical Contact Committee of the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association. These organizations have

generously responded to the requests by the secretary of the Council on Pharmacy and Chemistry for their reports and for information. The "Eleventh Report of the Combined Contact Committee of the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association," and two more recent reports of this Committee (received Nov. 23, 1933, and April 23, 1934) have been used as sources of material in the preparation of the present article. In the last report of the subcommittee of the Combined Contact Committee of the A. D. M. A. and the A. P. M. A. definite recommendations as to the testing of ampules were made, and these changes were to be incorporated in the National Formulary Bulletin. Details of these recommendations will be given in a later section of this article.

The secretary of the Council sent a questionnaire to the manufacturers of ampule preparations whose products are listed in New and Nonofficial Remedies. The replies to the questionnaire were placed in the hands of a referee of the Council on Pharmacy and Chemistry charged with the preparation of a report. The purpose of this report was chiefly to place on record information of interest to members of the Council, manufacturers of ampule preparations, the Food and Drug Administration and the organizations concerned with the question of the sterility of the contents of ampules of injectable materials. Neither the referee nor any one else as far as he knows has any reliable information on the incidence of bacterial contamination of these products and, of more significance, the incidence of infection due directly to the injection of ampuled material contaminated with pathogenic bacteria. Without this information it is not wise to attempt to recommend special regulatory rules.

It is obvious, however, that these injectable preparations should be sterile and the advisability of the adoption of standard methods of testing for sterility is clearly indicated. In view of the fact that this question is under discussion by other bodies as directly concerned as the Council, no specific action was taken by the Council, but its information and the opinions expressed in the reports were placed at the disposal of all interested groups, in the expectation that by a joint action a uniform and effective system of testing for sterility will be instituted.

In correlating the statements obtained in the replies from various manufacturers, some means of classification that would indicate the type of ampule preparations concerned was deemed necessary. For this purpose there was made a systematic grouping of the various injectable ampule, vial and syringe preparations that are described in N. N. R. In many cases it was found that manufacturers marketed preparations belonging to only one or two of these groups.

Injectable ampule and other preparations have been classified as follows:

**GROUP I Biologic**—This class includes serums, vaccines, bacterial toxins and modified toxins, allergenic and pollen extracts, gland preparations, and other products made by extraction of plant or animal tissue. All products of this class may be considered very susceptible to bacterial contamination.

**GROUP II Chemical**—Chemical substances which are actively bactericidal, such as soluble mercury salts, salts of other heavy metals, and other antiseptics.

**GROUP III Chemical**—Chemical substances in which bacteria and molds may grow, such as dextrose, glucosides, and preparations containing sugars or nonantiseptic carbon compounds.

**GROUP IV Chemical**—Products in which the growth of bacteria is not likely but which are not bactericidal and therefore may contain viable bacteria or spores. Most organic and inorganic substances belong in this class. Vegetable oil suspensions of insoluble mercury, bismuth and arsenic compounds are also included in this class because it is believed that the compounds may not be sufficiently soluble to have a bactericidal action. Some chemical compounds containing preservatives are also included because the preservatives are not present in high enough concentration to kill spores or resistant bacteria, although they may inhibit their growth.

Although the names of manufacturers and specific quotations from their replies to the questionnaire were included in the report presented to the Council on Pharmacy and Chemistry by the referee, it was considered advisable to omit from the

present article the names of the manufacturers who furnished the information here presented. For the sake of brevity only a summary is given of the data obtained.

Reports were received from twenty-six manufacturers out of the total of approximately thirty who have injectable ampule preparations listed in N N R. Of these twenty-six manufacturers, eight produce only ampule preparations belonging to biologic group I, four produce only ampule preparations in group IV, three produce ampule preparations in groups I, II, III, and IV, and five produce ampule preparations in groups III and IV. Ampule preparations of five other manufacturers are grouped as follows: I and III, I and IV, II and IV, II, III and IV, and III only. One manufacturer produces only ampule preparations in the form of dry powders to be dissolved and injected. Recently this manufacturer has presented for consideration by the Council an ampule solution of a chemical substance which would be classed in group IV.

The accompanying table summarizes the methods used for testing the sterility of ampules. Column one of the table shows the number of manufacturers having ampule products in each of the four groups. The second column shows the number of manufacturers producing products of the group indicated who use the National Institute of Health method, the third column shows the number using other methods of testing sterility, and the fourth column shows the number not testing for sterility.

Methods Used for Testing Sterility of Ampules

Group	Total Firms Producing Ampule Preparations in Group	Number Using National Institute of Health Method	Number Using Other Methods	Number Not Testing for Sterility
I Biologic	13	11	2	0
II Chemical	5	3	1	1
III Chemical	11	5	0	1
IV Chemical	15	0	7	2

From a consideration of this summary it may be seen that all of the reporting manufacturers who market products belonging to the biologic group I, with two exceptions, use a standard method of testing identical with or closely similar to the National Institute of Health method. One of the two manufacturers who use different methods reported a method of sterilizing and gave details as to the method of testing sterility that appear adequate. The other firm uses the official British method, the details of which are not at hand. From this survey it seems probable that practically all injectable preparations belonging to the biologic group I are adequately tested for sterility, in most cases by the National Institute of Health method, which up to very recently has been the only standard method for testing ampule sterility.

With regard to the chemical groups II, III and IV, the situation is somewhat different. It may be seen from the accompanying table that methods of testing these products are about equally divided between that of the National Institute of Health and other methods, which vary considerably in their degree of effectiveness.

Replies from some of the firms indicate that manufacturers who have reported that they use the National Institute of Health method actually use this method as a whole only for biologic preparations and apply it in a modified form to other classes of ampule preparations.

Eleven firms offer ampule preparations belonging to group III, preparations that will support the growth of bacteria, molds or yeasts. Five of these manufacturers use the National Institute of Health method for determining sterility. Four others reported methods that were not standard. For the most part these methods seemed to be at least partially effective in detecting contamination but in a few cases left something to be desired in regard to their adequacy. One firm, although stating that it tested for sterility, gave no details of the tests used. The eleventh firm of this group markets its ampule preparations without testing for sterility and the methods of sterilization used by this manufacturer do not seem certain enough to justify selling their product without sterility tests. Of the eleven firms manufacturing products in group III, only two definitely stated

in their reports that their preparations in this group were tested by special methods for molds.

Of the fifteen firms manufacturing ampule products in group IV, six use the National Institute of Health method of testing and one firm uses a method closely similar to this. Three firms offering products in this class have their products manufactured in Europe. Of these three, two gave no details of testing but indicated that their ampules were tested bacteriologically. The third gave enough details to indicate that the methods of testing as used were probably adequate. Of the remaining five firms in this group, two do no sterility tests on their products and the other three use methods of testing that are open to question as to their efficiency.

With regard to the ampule products of group II, substances that are self sterilizing, the opinion of manufacturers seems divided. Some firms have stated in letters that they test products of this class for sterility, whereas one or two others state that they do not test these products. The data from five firms presented in the table may not be an accurate statement of the status of testing of products of this class, since no definite statement on this point was made in most of the replies received.

One manufacturer offers several dry preparations sealed in ampules. Apparently no effort is made to keep these preparations sterile. Unless sterilization is carried out on the solutions of such products before use, it seems probable that both bacteria and spores may be carried over in the injected solution prepared from these dry powders.

Since several of the manufacturers in statements to the Council described in detail the recommendations of the National Institute of Health, a quotation of certain parts of this memorandum is given.\* Most of the details of preparing culture mediums and sterilizing apparatus are omitted.

Memorandum of Details Under Section 36, Regulations of Biologic Products U. S. Public Health Service, Miscellaneous Publication No. 10 Aug. 1 1923.

Bacterial tests are required to show sterility as regards organisms which will grow at ordinary temperatures for all products except vaccine virus.

Though preliminary tests on various media such as glycerin agar, ascorbic acid agar, etc. are to be used when the organism used in the manufacture of the product will not grow readily on ordinary media, the routine medium for testing sterility of all products is made as follows:

To 8 kilograms of ground fresh meat freed from fat there is added 16 liters of distilled water and the mixture is infused in the ice chest 24 hours. Sixteen liters of juice are squeezed out, heated in steam for one hour, filtered through moistened paper, brought up to the original weight and sufficient sodium hyaluronate added to make the reaction of the final broth in the fermentation tubes 0.5 per cent acid to phenolphthalein or 7.5 on the scale of hydrogen ion concentration. 5 grams of sodium chloride per liter are mixed in and 10 grams of dry peptone per liter are placed on top of the infusion which is then heated in steam for one-half hour.

Dextrose is added to a concentration of 0.03 per cent if there is not sufficient muscle sugar present in the broth.

The broth is filtered through moist paper and placed in glass capped Smith fermentation tubes containing at least 25 cc.—each with a seal of at least 1.0 cm. in the open arm—and autoclaved at 15 lbs. for 20 minutes. The Smith fermentation tubes should be in racks which facilitate tipping oxygen bubbles out of the long arm when hot or which allow such bubbles to flow out of the tubes while the heating is going on and which permit ready inspection of all parts of the tube for growth.

Planting is done within 5 hours after the broth has cooled. In general five drops of the fluid to be examined are planted in one tube and 20 drops in another tube. These are incubated at 37° C. for 7 days. The tubes should be examined on the 2nd, 4th and 7th days after planting and agitated only after 48 hours incubation to insure initial anaerobiosis, the lowest part of the bend should be examined for slight growths as well as both arms. In case the material is turbid (antirabic virus, etc.) transplants to fresh fermentation tubes as well as smears should be made on the seventh day.

The referee suggested several changes in this description of the preparation of this medium.

1. Omit the statement 0.5 per cent acid to phenolphthalein, as that method of titration and adjustment of reaction is now almost obsolete.

\* While these matters were under consideration by the Council and other interested organizations the United States Public Health Service issued a series of new Regulations for the Sale of Viruses, Serums, Toxins and Analogous Products in the District of Columbia and in Interstate Traffic approved March 13 1934 and published as Miscellaneous Publication No. 10, U. S. Treasury Department Public Health Service. A revised Memorandum of Details has not yet been issued by the Public Health Service. It is anticipated that within the next six months the National Institute of Health will issue a new 'Memorandum of Details' containing statements of its requirements and methods for testing the sterility of the contents of ampules.

2 Use the expression  $pH\ 7.5$  in place of the words 7.5 on the scale of hydrogen ion concentration, as  $pH$  and hydrogen ion concentration are expressions with very different meanings

3 Change the directions to provide for titration and adjustment of the reaction after the addition of the peptone. Most peptone preparations are acid. Hence titration before the solution of the peptone in the meat infusion may be unreliable as an index of the amount of alkali needed to make the reaction of the final mixture  $pH\ 7.5$

4 Use the word anaerobiosis in place of 'anaerobiasis'

Following the directions for the preparation and tubing of the medium, the memorandum gives directions for sterility tests on bulk products and on final containers, stating the amount to be planted, the number of final containers to be tested, and the procedure to be followed if contaminations are found

The Eleventh Report of the Combined Contact Committee of the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association, published Oct 27, 1932, makes the following recommendations in regard to ampule preparations

It is recommended that

*First*—All ampuls of glandular products which are essentially preparations of biologic origin shall be tested for sterility according to the prevailing National Institute of Health method for testing biologic products for sterility

*Second*—All ampul solutions containing germicidal substances in sufficient concentration to render them self sterilizing may be marketed without sterility testing

*Third*—The following provisional test is to be applied to all other ampul solutions until such time as more definite tests may be elaborated

The report then recommends a method of testing ampules for sterility which is essentially the same as the National Institute of Health method

More recently the Subcommittee on Standard Methods for Testing Ampoule Solutions for Sterility, American Drug Manufacturers, has made a report in which it is recommended that all manufacturers adopt standard methods of testing sterility. The report indicates that various modifications in the National Institute of Health method will have to be made in order to be applicable to the various types of existing ampule solutions, the diverse nature of ampule solutions being such that no one method is applicable to all of them

The classification of ampule solutions suggested by the committee is as follows

*Group I* All ampoule solutions prepared from gland products which are essentially protein preparations of broad biologic origin. Such ampoules may contain nutritive material which would make for ease in discovering contamination. This group could well be tested for sterility by application of the present National Institute of Health method which is applicable to this type of preparation and which would reveal possible harmful contamination

*Group II* Products containing germicidal substances in sufficient concentration to render the ampoule solutions adequately self sterilizing. This group would also include preparations containing chemicals which because of the reaction of the solutions in which they are offered become effective sterilizing agents

*Group III* Ampoule solutions containing sugars or other substances favorable to the growth of molds and/or yeasts

*Group IV* Ampoule solutions containing chemical substances not included in groups I, II and III

This grouping of products corresponds fairly closely to the grouping used by the referee in the report to the Council. The categories and numbering are the same. The referee believed that the grouping used in his report has the advantage of being more specific and inclusive and more adapted to the bacteriologic requirements. The definition of group IV of the subcommittee "Ampoule solutions containing chemical substances not included in groups I, II and III" seems to the referee to be too indefinite to be serviceable. Further study may indicate the need for a miscellaneous group, but the establishment of such an ill defined class should be avoided if possible

The recommendations of the Subcommittee on Standard Methods for Testing Ampoule Solutions for Sterility of the American Drug Manufacturers are as follows

We recommend that this committee be empowered to undertake the testing that will enable the classification of ampoule solutions in accordance with the above outline and to elaborate suitable standard methods for testing the members of groups III and IV and

Inasmuch as the National Formulary Committee has issued a proposed outline covering the sterility testing of ampoule solutions and action at this time is necessary

It is the recommendation of this committee that the following be submitted to the National Formulary Revision Committee for inclusion in the forthcoming revision of the National Formulary

There is then given a series of recommendations identical with those already quoted from the Eleventh Report of the Contact Committees of the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association

An examination of the section of the National Formulary Bulletin of Sept 14, 1933, pp 1163-1165, dealing with sterility tests on ampules shows that the recommendations contained therein are based on those which have been quoted. The paragraph on the number of ampules taken for sterility test is copied directly from the Eleventh Annual Report of the Combined Contact Committees of the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association. The details on preparation of culture mediums and tests on bulk and final containers are a synopsis of the recommendations given in the National Institute of Health Memorandum of Details under section 36, Regulations of Biologic Products, except that in the National Formulary directions for preparing the medium, 0.03 per cent of dextrose is added as a routine. In this instance the directions fail to state that the addition of the dextrose, in the form of a sterile 10 per cent solution, should be done with sterile precautions

At a meeting of the Combined Contact Committee of the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association held in Washington beginning Feb 5, 1934, several recommended revisions in the section on ampules of the National Formulary Bulletin were adopted. These are summarized as follows

1 It was decided to omit the requirement for sterility tests on ampules of bismuth subsalicylate, mercury salicylate, mercury succinimide and methenamine

2 The committee adopted a new method of testing ampule solutions in oil. This is quoted as follows

*Sterility Test for Ampoule Solutions in Oil* Media used Standard N I H broth containing 0.03% dextrose

Quantities of 250 cc each are filled into 500 cc flasks and sterilized in the autoclave at 15 pounds pressure for 15 minutes

Plant the contents of each ampoule (but not more than 5 cc) into a 500 cc flask containing 250 cc of medium. Incubate the flasks for 4 days at 37 C shaking the flasks thoroughly twice each day. At the end of the incubation period inoculate 6 fermentation tubes from each flask three with 5 drops and three with 20 drops transferred by means of a sterile pipette. The fermentation tubes are then incubated for 7 days at 37 C and are examined for evidence of growth on the second fourth and seventh day after planting

3 Recommended besides the standard test for bacteria an additional test for molds in ampules of dextrose and ampules of dextrose and sodium chloride as follows

*Ampoules of Dextrose* Add additional test as follows

With the additional test being made for the determination of yeasts and/or molds

Medium	
Agar	20 Gm
Peptone	10 Gm
Maltose	40 Gm
N/10 Hydrochloric acid	
Tap water sufficient quantity to make 1000 cc	

Dissolve the agar, peptone and maltose in the water by means of heat add a sufficient amount of the N/10 hydrochloric acid to bring the  $pH$  to approximately 5.5 when tested colorimetrically with methyl red. Fill 10 cc quantities into test tubes approximately 18 X 144 mm in size and sterilize by Process D. Incubate the tubes for one day at 37 C and for 3 days at room temperature as a check on the sterilization methods

From each sample plant 4 tubes of medium two with 5 drops and two with 10 drops. Spread the liquid over the entire surface of the slant by gently tilting the tube after planting. Incubate the tubes for 4 days at room temperature (20 to 25) and 3 days at 37 C. Examine the tubes at 24 hour intervals for growth spreading the film of liquid over the surface each day by tilting the tubes. If evidences of growth appear on any of the tubes they should be left undisturbed in order that colony growth may proceed

Both of the newly recommended tests represent a significant step in advance. The test for sterility of ampule solutions in oil is apparently designed to separate spores and bacteria from the insoluble oily layer and bring them in contact with the nutritive medium. A special test for the detection of molds in ampule solutions of group III seems particularly desirable. Many of these organisms do not grow well at 37 C in liquid mediums, therefore the use of some such medium as Sabouraud's agar and incubation at 22 C is advisable. Although most organisms that grow only under these conditions are nonpathogenic their detection serves as an index of nonsterility

The Contact Committee has made no very definite recommendations with regard to testing ampule preparations containing various chemical substances such as those we have classified in groups II and IV. Obviously the question of whether or not a given ampule preparation is self sterilizing can be settled only by a test in which the bactericidal power of the solution against several species of bacteria, and bacterial spores, is determined. It does not seem safe to call an ampule preparation self sterilizing merely on presumptive evidence. But if an ampule solution can be shown by satisfactory tests to be self sterilizing, the omission of sterility tests on the product might be justified by the saving of trouble and expense.

The question remains open as to whether or not the ampule preparations of diverse nature included in the three groups of chemical preparations can all be adequately tested for sterility by a single standard method such as that of the National Institute of Health. In a recent letter one firm has stated that it does not consider the latter method adequate for the testing of its ampule product, which is of a biologic nature. It has supplemented it by special tests for anaerobes.

The Memorandum of Details under section 36 Regulations of Biological Products, contains in addition to the routine test already quoted, directions for the testing of vaccine virus for anaerobes, but there is no information as to how widely this special method has been applied to other products.

The present status of the National Institute of Health method of testing sterility is probably best summarized by a recent letter from P. B. Dunbar, assistant chief of the Food and Drug Administration:

The investigation of sterility of ampule preparations by the Administration mentioned on the second page of the report has been under way for some time and is still continuing. Since this investigation is not yet complete it is perhaps somewhat premature to draw any definite conclusions concerning the incidence of bacterial contamination of such products. However in a large number of examinations of ampule solutions made since the recent survey was begun in 1933 bacteriologists of the Administration have encountered no instability. In making the examination the Administration bacteriologists have followed the method recommended by the National Institute of Health. The procedures recommended by the National Institute of Health have been found readily applicable to the various types of ampule preparations included in the survey. Nevertheless it is possible that some modifications of the recommended method might be made to permit the development of a simple standard method that will have a universal application in all laboratories for all types of ampule solutions. The Food and Drug Administration has not been able to conduct any research work to test possible changes to improve or simplify the method recommended by the National Institute of Health. Consequently, we cannot offer any constructive criticism of the method at this time.

Most of the recommendations for standard tests so far drawn up by the American Drug Manufacturers Association, American Pharmaceutical Manufacturers' Association, the National Formulary Committee, and the Committee of Revision of the Pharmacopoeia of the United States and those submitted by several of the manufacturers are based directly on the Memorandum of Details under section 36 Regulations of Biologic Products, U. S. Public Health Service. This memorandum gives the most detailed and thorough description of testing sterility of any of the recommendations so far submitted, but, as has been indicated, revision of the directions given may be necessary before an effective standard method can be established. The further recommendations from the Contact Committee of additional tests for possible contamination in ampule solutions in oil, and the tests for molds and/or yeasts are indications of constructive work on the part of the manufacturers.

In addition to the methods already described, the U. S. Pharmacopoeia proposes to have a method of procedure for determining the sterility of distilled water and physiologic solution of sodium chloride. The preparation of the medium and the details of testing are very similar to those of the National Institute of Health except that the medium contains 1 cc of 10 per cent sterile dextrose solution added to each tube of 25 cc and the directions call for the adjustment of the reaction to pH 7.6 after the addition of the peptone.

#### MULTIPLE DOSE AMPULES

The referee has seen infections following the injection of material from multiple dose ampules. These have been due to contamination of the material by physicians when they withdrew portions of fluid from a large ampule and later used the remaining material for other injections. In practice large

ampules, once opened, may be exposed to contamination repeatedly during several hours. The referee knows of one instance in which severe cellulitis of the arms of recipients of injections were caused by injection of material (originally sterile), from a large ampule, which had been opened and partially used one week previously. To prevent accidents of this sort, the referee believes that multiple dose ampules should contain a bactericidal agent in sufficient concentration to prevent the multiplication of bacteria and ultimately to kill bacteria in the material.

## Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING  
GENERAL DECISION  
RAYMOND HERTWIG Secretary

### SPECIAL PURPOSE FOODS FOR DIETS RESTRICTED IN DEXTROSE FORMERS

Special Purpose Foods, such as special bread, cake and flour for diets restricted in dextrose formers, to be eligible for acceptance, excepting in cases of special adaptability, shall contain dextrose formers in an amount not greater than 33 Gm of dextrose per hundred cubic centimeters (computing the dextrose equivalence as the carbohydrate, plus 58 per cent of the protein, plus 10 per cent of the fat content of the food). The labels and advertising shall comply with the Committee Rule "Special Purpose Foods."

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

### FISHER'S BISCUIT MIX

*Manufacturer*—Fisher Flouring Mills Company, Seattle

*Description*—Biscuit mix requiring only addition of liquid for baking. Contains bleached short patent flour, hydrogenated vegetable oil, salt, skim milk, sodium bicarbonate, sucrose, dextrose, calcium acid phosphate, calcium lactate and sodium acid pyrophosphate.

*Manufacture*—The nonfat ingredients are thoroughly mixed, the shortening is "cut" into the flour by special mixing equipment. The product is packed in cartons.

*Analysis* (submitted by manufacturer) —

	per cent
Moisture	10.7
Ash	4.1
Fat (ether extraction method)	14.0
Protein (N × 5.7)	7.6
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	63.3

*Calories*—41 per gram 116 per ounce

### VELVO PASTEURIZED HOMOGENIZED MILK

*Distributor*—Oakland Dairy, Pontiac, Mich

*Description*—Bottled, pasteurized homogenized milk

*Preparation*—Milk obtained from producers under supervision of the Michigan State Department of Health and the City of Pontiac Department of Health is tested for milk fat, sediment and its reaction to methylene blue. Milk passing these tests is pasteurized by the holding method (63 C for thirty minutes), cooled to 54 C, homogenized under 3,000 pounds pressure cooled to 7 C and automatically filled in bottles.

*Analysis* (submitted by distributor)—Standardized to contain not less than 36 per cent milk fat.

*Calories*—07 per gram, 20 per ounce

*Claims of Distributor*—The cream does not separate

## THE TREND OF INFECTIOUS DISEASES OF CHILDHOOD

The constant change in the frequency of disorders of the human body is well illustrated by the decreasing incidence of infectious diseases in civilized countries. Probably the most striking example, especially for those whose medical memories extend thirty years or more, is typhoid. At present the trends of other infectious diseases, such as diphtheria,<sup>1</sup> are of particular interest.

Useful recording and statistical interpretations of disease trends are those appearing in the Epidemiological Reports of the Health Section of the Secretariat of the League of Nations. In a recent issue<sup>2</sup> it was proposed to show that a decline has occurred in the deaths caused by whooping cough and measles similar if not equivalent to that in diphtheria and scarlet fever. Attention was also drawn to the relative social importance of these four infectious diseases of childhood, since "the traditional fear inspired by scarlet fever and diphtheria is no more justifiable than the indifference shown by public opinion and even perhaps by some health authorities as regards measles and whooping cough." In order to estimate the relative social significance of these diseases it is necessary to consider not only the death rates but also their morbidity, as shown both by the statistics of reported cases and by the results of inquiries to children and adolescents concerning the infectious diseases they have had.

Only in England and Wales are the statistics previous to 1900 sufficiently reliable to permit a study of mortality from these four diseases since 1856. These statistics bring out clearly the absolute and relative preponderance of scarlet fever until 1880. Up to that year scarlet fever caused nearly 40 per cent of the deaths attributed to the four diseases. Since 1916 scarlet fever has been responsible for less than 6 per cent, on the average, of the deaths from these diseases. The death rate fell gradually from 264.6 per hundred

thousand in 1861-1865 to 5.5 in 1926-1930, a decline of nearly 98 per cent. Diphtheria also declined but began from a lower level and did not fall quite so low. Hence the proportion of the deaths due to diphtheria, which averaged about a fifth until 1890, has now risen to about a fourth of all the deaths from these four diseases. Whooping cough and measles, which also caused about a fifth each of the total deaths from these diseases at the middle of the last century, have slowly increased their respective proportions and are now each responsible for more than a third, in spite of the diminution in actual number of deaths they cause (68 and 82 per cent, respectively). Until 1880 the deaths from whooping cough had barely begun to decrease, but since then the decline has continued uninterruptedly. As regards measles, however, the mortality fluctuated unevenly until 1915 and it is only since that year that the decline has taken place. The courses followed by these four contagious diseases of childhood do not exactly synchronize, so that the decline in their mortality cannot be attributed to a single cause. The drop in the proportion of children in the general population cannot be put forward as a cause, since the rates are calculated on the infantile population (0-15 years).

In comparing the death rates from these four diseases in different countries, the essential common trait is a decrease for every disease in every country. In some countries, however, the initial death rate was higher than others at the beginning of the century and the decrease since that time still leaves them with a higher death rate than others. It seems, therefore, that the various countries are passing through different stages of an identical evolution.

As far as its mortality is concerned and in spite of the falling off during the last few decades, diphtheria remains one of the most serious of children's diseases. Whooping cough and measles also remain serious, and this would be more obvious were it not for the fact that a number of secondary cases of bronchopneumonia following these diseases are still classified under the heading "bronchopneumonia." These two diseases, and particularly measles, deserve more attention than the careless indifference too often shown them by the public.

When these studies are removed from the realm of pure statistics, certain facts are seen to take on an important significance. The decline in the mortality from scarlet fever and diphtheria is in general well recognized, that from the other two diseases not so well. The relatively large mortality from whooping cough and measles is certainly not grasped by the public and probably not by a considerable element of the medical profession. This situation should receive notice by health authorities and medical schools especially. In the latter a lag in teaching emphasis is to be expected, but such emphasis should not remain completely static. By way of example, many medical

<sup>1</sup> Diphtheria Mortality in Large Cities of the United States in 1933. Eleventh Annual Report J. A. M. A. 102:1758 (May 26) 1934.

<sup>2</sup> Relative Importance of the Principal Infectious Diseases of Childhood. Epidemiological Report of the Health Section of the Secretariat League of Nations R. E. 173:109 (Nos. 5-6) 1931.

graduates, even recent ones, are conscious of a time and effort spent on typhoid entirely incommensurate with the present medical importance of that disease in most districts. Similarly it should now be obvious that greater efforts should be made in instruction on measles and whooping cough than is generally allowed.

### CLIMATE AND HEALTH

The relation of "climate" to human health and disease has intrigued both physicians and the public, at least since the writing of the chapter "Of Airs, Waters and Places" in the works of Hippocrates. Until the microbic theory began to be seriously studied, in fact, almost every discussion of disease opened with the observed relationship of the condition to season, locality, temperature or other "climatic" factors. Thus, Sydenham<sup>1</sup> introduces one chapter by "The foregoing Winter being extremely cold, and the Frost continuing without any intermission till Spring, it thaw'd suddenly at the end of March, in the year 1665, and Inflammations of the Lungs, Pleurisies, Quinsies, and such like inflammatory Diseases, made great slaughter on a sudden, and at the same time a continual Epidemick Fever appear'd."

One of the difficulties in scientifically relating disease to climate is the somewhat vague definition of the term. Smith<sup>2</sup> in his recent presidential address before the British Medical Association defines "climate" as "indicating all the solar and terrestrial factors and influences which affect animal and vegetable life, including sunlight, atmospheric temperature, humidity and pressure, movement of air, and prevailing winds and whilst including airs, also embracing waters and places." With a definition as broad as this it is entirely impossible to relate "climate" in any scientific sense with any bodily or mental modification.

The hours and intensity of sunlight can certainly be included as one of the important factors in "climate." Few could be found to disagree with Smith when he says that "whilst the sun is our greatest natural friend, he can, if regarded with disrespect or insolence, become an equally potent foe." It is the duty of the profession to counsel that moderation is essential to the successful practice of any theory. In tuberculosis, at least, this thesis seems to be amply proved. Here again, however, it is virtually axiomatic that anything in excess of certain physiologic limits is harmful. Such redundancy is of doubtful value.

It would seem time that the veil surrounding the somatic effects of climatic factors be lifted further. The most confusing feature of the problem has been the inclusion of essentially unrelated elements. Thus Smith states that "often a climate with frequent but moderate variations will prove beneficial, the more so

if combined with a regular rhythm of rest, sleep, open-air exercise, and a properly supervised and dispensed diet, beautiful surroundings, changes of scene and of manner of life, all helping to encourage the invalid." If all these things help, what is the exact beneficial effect, might one well ask, of increased direct sunlight, higher temperature, lower humidity or increased wind velocity?

The outlook for improving the indications for a "change of climate" is not hopeless, however. Such change is not thought necessary for hookworm disease, not always for malaria, and there is a considerable body of opinion that thinks it is not necessary for the adequate treatment of pulmonary tuberculosis. Complete nihilism in this respect is also probably not justified. Any belief that has existed as long and persistently as the value or harm of a specific climate in all probability has some foundation in fact. Coburn's<sup>3</sup> work on the effect of Puerto Rican conditions on rheumatic fever is a good example of what may be done. It is not wholly immaterial that it is the infrequency of hemolytic streptococci rather than the temperature that has the favorable effect. The enthusiastic prospectus of this or that resort or spa should give way to a more exact knowledge of the benefits that should accrue to those who change their locality. The medical profession needs some foundation other than the financial status of the patient for advising for or against a change of climate. This amounts to a challenge.

### THE STERILITY OF DRUGS IN AMPULES

About a year ago Gershenfeld,<sup>1</sup> of the Philadelphia College of Pharmacy and Science, called attention to the fact that solutions marketed in ampules, generally considered to be sterile, may occasionally be contaminated with pathogenic organisms. He reported two cases of suppuration that developed in patients following the injection of the contents of ampules, both from the same batch, although in each case the usual aseptic precautions were taken by the physician. Two ampules from this batch were then examined and each revealed the presence, in pure culture, of *Staphylococcus aureus*. From a brief survey then made by Gershenfeld, it appeared that many firms fail to indicate on the labels of ampule preparations whether or not these are sterile. The physician ordinarily makes the tacit assumption, when he administers to a patient the contents of a sealed container of this type, that adequate precautions have been taken by the manufacturer to assure the absence of viable micro-organisms. While in the majority of instances this belief is no doubt warranted, it appears that this is not universally the case. When an infection has occurred from a parenteral injection, it is usually impossible to determine whether this was

<sup>1</sup> Sydenham Thomas. *Practice of Physick* ed 8. London: J. Darby, 1722.

<sup>2</sup> Smith S. W. *Climate and Health*. *Brit. M. J.* 2: 153 (July 28) 1934.

<sup>3</sup> Coburn A. F. *The Factor of Infection in the Rheumatic State*. Baltimore: Williams & Wilkins Company, 1931.

<sup>1</sup> Gershenfeld Louis. *Control of the Traffic in and Labeling of Ampules and Medicaments for Parenteral Administration*. *Am. J. Pharmacy* 105: 155 (April) 1933.

due to the solution employed or to a slip in technique. For this reason evidence is not available either as to the approximate incidence of contamination or as to the occurrence of infections from the use of nonsterile products. The Food and Drugs Administration endeavors to keep as complete a check as possible on such of these preparations as come under its jurisdiction by reason of claims made on the labels, but an extensive survey undertaken by this agency after the appearance of Gershenfeld's article has not yet been completed.

The Council on Pharmacy and Chemistry recently undertook to study this problem, and its detailed report appears elsewhere in this issue (p 677). A questionnaire was sent to all manufacturers having products of this type accepted for New and Nonofficial Remedies, requesting information as to methods employed for sterilizing and for testing for sterility. It appeared from the replies received that wide divergence exists among various firms in the methods used for sterilization of the contents of ampules and in subsequent testing for absence of contamination in the finished products. Practically all the biologic products that come under the supervision of the National Institute of Health appear to be adequately tested for sterility. In the case of chemical substances and solutions of the various types listed in the Council's report, the methods employed by most of the firms appear also in large part to be adequate. However, in a significant number of instances these do not appear to be such as to assure absence of bacterial contamination.

No standard method is employed by all firms, and the procedures variously used differ greatly in their effectiveness. In a few cases the final product is not tested at all and, in the case of some dry preparations to be dissolved before use, the substance may not even be sterilized. In the latter case, of course, contamination would not ordinarily be serious, yet it is conceivable that severe infection might result from the use of a solution made under otherwise aseptic precautions from such a powder. Multiple dose ampules sealed with rubber stoppers involve a special problem, as the solution even if originally sterile, may become contaminated during withdrawal of a dose. It is the Council's opinion that such preparations should contain a potent bactericide in proper concentration.

The Council found in its investigation that a number of other agencies were interested in assuring the sterility of ampule preparations and were taking steps to establish standard methods to be employed by commercial organizations. These were the Committee on Revision of the Pharmacopeia of the United States, the National Formulary Committee, the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association. Most of the recommendations made have been based on the regulations issued by the United States Public Health Service. It is anticipated that the problems involved will reach

an early solution and that such procedures as are necessary to assure with reasonable certainty the sterility of preparations marketed for parenteral use will soon be extensively practiced.

## Current Comment

### THE DIONNE QUINTUPLETS

Elsewhere (p 673) appears the account by Dr A R Dafoe of the birth and successful rearing to two months' growth of quintuplets. The incident is notable—apparently the first of its kind to occur in the history of medicine. True, there have been previous records of quintuplets, perhaps as many as from thirty-two to thirty-five instances, but, as Dr Dafoe points out, in no previous instance have quintuplets ever reached the age of two months. The incident, while extraordinary, is useful as well in pointing a moral. Callander, Ontario, as every one now knows, is far from being a metropolitan community. Its population is around 600 people and Dr Dafoe is the only doctor there. Nevertheless, to him there came an extraordinary opportunity. With the traditions of medicine and an excellent sense of the ethical requirements of the situation, he met the occasion. As evidence, one needs only to read his account of the incident in the phraseology with which it was sent to *THE JOURNAL*. His conduct of the case and his relations to the public in connection with it have been exemplary. As one gazes on the picture of the midwife and reads the record of the conditions under which these children were born and developed, one realizes to some extent also how futile is much of the superscientific and pseudoscientific discussion that has been published in recent years on the problems of maternal mortality and infant care. There are many lessons for scientific medicine in this incident.

### HANDWRITING OF CRIMINALS

In a recent report, Quinan<sup>1</sup> has described the results of efforts to differentiate the handwriting movements of convicted murderers from those of convicted forgers. One hundred each of murderers, forgers and unselected noncriminals were examined. In addition, six abattoir "killers" were studied. The same model sentence was written by all the subjects, and the time required, the angular inclination of the letters, the total running length along the base line and the configuration of the letters were recorded. It appears that bradygraphia is characteristic of murderers, for this group required 101 seconds to complete the model sentence, whereas the times for forgers and noncriminals were 68 and 49 seconds respectively. The running length was somewhat greater for the forgers than for the other groups. The total angularity of the letters was noted. The coarse, sprawling letters instead of smooth and rounded loops were evidently made by jerky movements of the pen. The numbers of angles were 469, 286 and 283 for the murderers, forgers and noncriminal groups.

<sup>1</sup> Quinan, Clarence. Handwriting of Criminals. *Arch Neurol & Psychiat* 32:30 (Aug) 1934.

respectively. The "spastic-ataxic" writing of the murderers was also characteristic of the six abattoir "killers." The writing of the forgers, in addition to being full and rounded in configuration, frequently showed eccentricities in the manner of crossing the t's as well as certain flourishes on terminal letters. Although without doubt many factors influence the character of a person's handwriting, it is of considerable interest that in these antisocial groups a correlation can be established between handwriting and the particular misdemeanor involved.

## Association News

### MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central daylight saving time. The next three broadcasts will be as follows:

September 13 Common Eye Troubles William C. Benedict, M.D.  
representing the meeting of the American Academy of Ophthalmology and Otolaryngology in Chicago  
September 20 Infantile Paralysis W. W. Bauer, M.D.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ARKANSAS

**Society News**—At a meeting of the Tri-County Medical Society in Prescott, June 28, the speakers were Drs. George V. Lewis on "Infections of the Hand," Grady W. Reagan "Treatment of Acute Complications of Gonorrhea," and Clyde D. Rodgers, "Care During Pregnancy." The speakers were from Little Rock.—Dr. Walter G. Eberle, Fort Smith addressed the Crawford County Medical Society, June 26, on "Fertilization of the Human Female."—The Washington and Benton county medical societies held their annual picnic session at Cave Springs, July 12, speakers were Drs. Sidney J. Wolfermann, Fort Smith, on "Significance of Jaundice," and Jesse D. Riley, State Sanatorium, "Pulmonary Tuberculosis." Dr. Harvey D. Wood, Fayetteville, the only living charter member of the Washington County society, spoke in recognition of that society's sixty-second anniversary.

### CALIFORNIA

**Personal**—The following promotions at the University of California School of Medicine, San Francisco, among others have been announced: Dr. Edward L. Munson, to professor of preventive medicine; Dr. Edward B. Shaw, to associate clinical professor of pediatrics; and Dr. Keene O. Haldeman, to assistant clinical professor of orthopedic surgery.

**More of the Eyesight Swindlers**—Warrants for the arrest of three persons posing as eye specialists have been taken out in California. The swindlers recently appeared in Long Beach, where they approached a Mr. J. O. Miller with practically the same story that has been frequently detailed in THE JOURNAL. A representative called on Mr. Miller, whose name had been obtained from the local optometrist. He examined his eyes, located what he called a cancerous growth, and called in a famous surgeon, who "happened" to be with the representative and who for \$200 performed an operation. Later the representative returned with the story that the surgeon had been killed in an accident, but before his death had turned all his patients over to another physician who was ready to make

the examination and prescribe the necessary treatment. Following the examination, it was decided that twenty-one treatments in a clinic in San Francisco were necessary, the cost to be \$500. When the victim said he could not make the trip and admitted having only \$300, the surgeon stated that a cure could be effected by using a belt for which Miller must put up a bond of \$500. Credit for the \$200 paid for the first operation was allowed, and the \$300 was accepted for the remainder of the bond. A few days later a man posing as an express agent told Miller that there was a delay in the delivery of the belt but that the money would be returned as soon as he returned the belt. Miller heard no more of the swindlers. The names used in this instance are Miles, Howard and Evans. The name Miles is used also in the Kentucky news item, March 17, page 849, and Oregon, August 11, page 419.

### COLORADO

**Tuberculosis Conference**—Announcement is made of the tentative program of the Rocky Mountain Tuberculosis Conference at the Antlers Hotel in Colorado Springs, September 17-19. The following physicians will participate, among others:

Charles W. Mills, Tucson, Ariz., "A Simple Method of Procedure in the Diagnosis of Pulmonary Tuberculosis";  
Robert B. Homan, El Paso, "X-Rays in the Diagnosis of Pulmonary Tuberculosis";  
Clinton E. Harris, Woodmen, "Differential Diagnosis of Intrathoracic Tumors and Pulmonary Tuberculosis";  
Lewis J. Moorman, Oklahoma City, "Congenital Cystic Diseases of the Lung";  
Philipp Schonwald, Seattle, "A Modification of the Blood Sedimentation Test in Pulmonary Tuberculosis";  
Carl H. Gellenthien, Valmore, N. M., "Temperature and Pulse Rate in Pulmonary Tuberculosis";  
Earle G. Brown, Topeka, Kan., "Progress in Tuberculosis Control in Kansas";  
Robert O. Brown, Santa Fe, "The New Mexico State Wide Health Survey";  
Henry Sewall, Denver, "Artificial Pneumothorax in Pulmonary Tuberculosis";  
Jay Arthur Myers, Minneapolis, "General Considerations in the Diagnosis of Childhood Tuberculosis";  
Leon G. Woodford, Everett, Wash., "Artificial Pneumothorax and Phrenicectomy";  
James H. Forsee, Denver, "Closed Intrapleural Pneumolysis";  
Sturley C. Davis and Charles A. Thomas, Tucson, "Thoracoplasty".

At the banquet Tuesday evening, Dr. Kendall Emerson, New York, managing director, National Tuberculosis Association, will discuss "The Future in Tuberculosis Control," and Dr. James J. Waring, Denver, "The Murphy-Forlanini Controversy."

### FLORIDA

**Campaign Against Mosquitoes**—The state health department is directing special campaign measures throughout Florida to prevent the spread of dengue fever, 800 cases of which were reported in a recent outbreak in Miami. In West Palm Beach, a feature of the campaign was a house to house canvass by FERA workers to detect mosquito breeding places.

**Society News**—At a meeting of the Dade County Medical Society in Miami, August 3, speakers were Drs. Charles D. Cleghorn and John W. Snyder, both of Miami, on "Skin Tumors" and "Gritti-Stokes Amputation for Gangrene of the Leg," respectively.—Speakers before the Leon-Gadsden-Liberty-Wakulla-Jefferson Counties Medical Society in Tallahassee July 19, included Drs. Robert F. Godard, Quincy, on "Causalgia," and Laurie L. Dozier, Tallahassee, "Prevention of Puerperal Infection."

### GEORGIA

**University News**—Dr. Newdigate M. Owensby, Atlanta, has been appointed professor of psychiatry at the University of Georgia Medical Department, Augusta, and Dr. James R. Garner, Atlanta, has been designated visiting professor of forensic medicine.

**Society News**—Speakers before the First District Medical Society, July 25, in Savannah, included Drs. Joseph Sumter Rhame, Charleston, S. C., on "Gastric Cancer," James E. Paullin, Atlanta, "Diagnosis and Treatment of Rheumatoid Arthritis," John W. Daniel, Savannah, "Treatment of Peptic Ulcers with High Protein Diet," Clinton R. Rimer, Savannah, "Acute Osteomyelitis of the Pelvic Bone," and Dr. Clarence L. Ayers, Toccoa, "The Unusual Necessity for Medical Organization of the Present Time."—At a meeting of the Fulton County Medical Society, August 16, Dr. Edwin S. Byrd gave a clinical talk on pernicious anemia and Drs. Calvin B. Stewart and John F. Denton presented a paper on carcinoma of the cervix uteri.

## ILLINOIS

**Health Program for the Colored Population**—A canvass of prevailing health conditions among preschool children is the first step in a health program among the colored population of the state to be conducted by the state department of health. During the first week in September a series of conferences will be held to conduct physical examinations of preschool children, the records of which will be used to draw up a practicable program to improve health conditions among the colored population, which is concentrated principally in St. Clair County.

**Epidemic Encephalitis Increases**—With sixty-five cases of epidemic encephalitis reported since August 1, the state health department announces a pronounced upward trend in the prevalence of the disease. Thirty-seven new cases were reported during the week ended August 25. Six cases occurred in Danville while Canton, Fulton County, and Bartonville, Peoria County, each reported three cases. There were five cases in Paris in Edgar County, where an epidemic occurred in 1932. The department reports that the majority of new cases are among elderly people.

## KANSAS

**Personal**—Dr. Clarence R. Hepler, Wichita, has resigned as health officer of Sedgwick County, effective July 1, to accept a position at the state hospital at Larned, it is reported. Dr. J. Carroll Montgomery, Topeka, has been appointed to succeed him—Dr. Herschel L. Hendricks, Iola, has been appointed health officer of Allen County, succeeding Dr. Adelbert R. Chambers.

**Brinkley Fails Again**—John R. Brinkley of Milford, "goat gland specialist" who sought nomination as a candidate for governor, was defeated in the recent primary, polling less than 70,000 votes out of a total of 300,000. Two years ago Brinkley received 244,607 votes as an independent candidate, according to *News-Week*.

## MAINE

**Dr. Hill Honored**—Dr. J. Frederick Hill, Waterville, was presented with a silver cocktail service at a celebration on his eightieth birthday, June 15. Among those present were Gov. Louis J. Brann, Dr. Edwin W. Gehring, president, Maine Medical Association, and the mayor of Waterville, L. Eugene Thayer.

**Clinical Meeting**—The second clinical meeting of the Maine Medical Association will be held in Portland, October 4-5. Clinical demonstrations in medicine and surgery will be held in the various hospitals. No formal papers will be presented. The Cumberland County Medical Society will entertain with a dinner Thursday evening, October 4. The first clinical meeting was held in Bangor, February 20-21, when the staff of the Eastern Maine General Hospital presented the program.

## MARYLAND

**Outbreak of Typhoid**—Twenty-eight cases of typhoid were traced to a benefit supper in Baltimore recently. Although the manner in which the supper served as a means of disseminating the disease has not been ascertained, according to *Baltimore Health News*, it has been learned that one person closely connected with the management of the affair was suffering from an apparently unrecognized ambulatory form of typhoid.

## MICHIGAN

**Personal**—Dr. Francis A. Hargrave, Palo, recently celebrated the fiftieth anniversary of his entrance into medical practice—Dr. John E. Gordon, epidemiologist of the Detroit Department of Health, will leave the department October 1 to join the staff of the Rockefeller Foundation in New York.—The American Legion, Charles A. Learned Post, number 1, honored the memory of Dr. Max Ballin, Detroit, through the adoption of a resolution eulogizing him as a physician and a soldier. Dr. Ballin died in March.—Dr. John L. Burkhart, who has practiced medicine in Big Rapids for fifty years, was guest of honor at a banquet, July 17, attended by more than 200 persons, including Governor Comstock.

## MINNESOTA

**Illegal Practitioner Sentenced**—Mrs. Letha Beach, alias Letha Byers, pleaded guilty to practicing healing without a basic science certificate when arraigned in district court, August 3, at Fergus Falls. Investigation by the state board of medical examiners disclosed that the woman had represented herself as a physician from Nebraska and had sold herb medicines

to two persons in Henning, collecting \$19 from two patients. It was said also that she represented herself as being connected with the medical profession in that vicinity but admitted when arrested that this was not true. It was further brought out that she had practiced the same type of "healing" in Redwood County in 1928. Judge Anton Thompson sentenced the woman to one year in the jail of Otter Tail County and placed her on probation until December 1935. She is to return the money to the persons at Henning and is to refrain from practicing healing in any form in the state.

**Northern Minnesota Meeting**—The annual session of the Northern Minnesota Medical Association will be held at the Elks Hotel in Brainerd, September 10-11. The scientific program is as follows:

Dr. Herbert H. Leibold, Parkers Prairie, Fractures, Diagnosis and Treatment in Rural Practice  
Dr. Ernest M. Hammes, St. Paul, Cerebral Arteriosclerosis  
Dr. Joseph C. Michael, Minneapolis, Recent Therapeutic Advances in Neurology  
Dr. Samuel H. Boyer, Jr., Duluth, Idiopathic Hypochromic Anemia  
Dr. James B. Carey, Minneapolis, Diagnosis and Management of Anemia  
Dr. Morris H. Nathanson, Minneapolis, Treatment of Cardiac Emergencies  
Dr. Robert L. Nelson, Duluth, Report on Meeting of the American Heart Association  
Dr. Edgar T. Herrmann, St. Paul, Present Status of Dinitrophenol  
Dr. Berton J. Branton, Willmar, Cost of Liability Insurance  
Dr. William H. Hengstler, St. Paul, Malpractice  
Dr. William T. Peyton, Minneapolis, Malignant Tumors Arising from Epithelioma of the Pharynx  
Dr. Chauncey A. McKinlay, Minneapolis, Treatment of Infertility Associated with Hypometabolism  
Dr. Lloyd F. Hawkinson, Brainerd, Endocrine Growth and Sex Deficiency  
Dr. Edward N. Peterson, Eveleth, Osteitis Fibrosa Cystica  
Dr. Norman P. Johnson, Minneapolis, Nonorganic Causes of Fatigue  
Dr. Edward H. Ryncarson, Rochester, Diagnosis and Treatment of Various Types of Goiter  
Dr. Gershom J. Thompson, Rochester, Prevention of Complications of Prostatic Resection  
Dr. Olaf J. Hagen, Moorhead, The Jaundiced Patient  
Dr. Edward Bratrud, Thief River Falls, Urography with Special Reference to the Differential Diagnosis of Kidney Conditions  
Dr. Frank J. Hirschboeck, Duluth, Medical Emergencies in the Chest

A banquet will be held at the Ransford Hotel, Monday evening, with Richard E. Scammon, Sc.D., Minneapolis, as toastmaster. An address on "Minnesota Man" will be delivered by Albert E. Jenks, Sc.D., professor of anthropology, University of Minnesota. Dr. Axel C. Baker, Fergus Falls, will give his presidential address on this occasion, and Dr. Francis J. Savage, St. Paul, president of the state medical association, will speak.

## MISSOURI

**Personal**—Dr. Hyman I. Spector, tuberculosis controller, has been appointed assistant health commissioner of St. Louis to succeed Dr. Paul J. Zentay, resigned, and Dr. Harold D. Choje, city epidemiologist, has resigned to accept an appointment as assistant director of the California State Department of Health.

## NEW YORK

**Quarantine Rules Modified**—Regulations in the sanitary code dealing with quarantine in cases of poliomyelitis, meningococcal meningitis, scarlet fever and diphtheria were amended at a recent meeting of the public health council. Under the new provisions, adults in a household in which there is a case of poliomyelitis or meningitis need not be quarantined. Adults in contact with cases of diphtheria or scarlet fever may continue to follow any vocation that does not involve handling of food or close association with children if the sick persons are properly isolated at home. Children in such households must be quarantined until the patient is released. The isolation period for scarlet fever was also reduced from thirty days to twenty-one days by the new regulations.

## New York City

**Report of Tuberculosis Committee**—Expansion of the city's facilities to the point at which 7,500 patients with tuberculosis can be cared for at one time was recommended by a special committee appointed by Dr. Sigismund S. Goldwater, commissioner of hospitals, several months ago to study the situation. This would mean 2,500 additional beds. There should be a central institution in each borough, the committee averred, for persons requiring relatively short periods of hospitalization, and three country institutions comprising about 1,400 beds for convalescents. The latter should be operated by the state and paid by the city for care of its patients, the committee believed. The Municipal Sanatorium at Otisville should be turned over to the state, the report declared. It was also suggested that the health and hospital departments each appoint a "chief of

tuberculosis" to coordinate the work of the two departments in this field. Until an adequate number of beds is provided, the committee recommended that patients be admitted to hospitals not by priority but by consideration of their condition, that is, those most likely to endanger the health of the community and those most in need of care should be admitted first. The hospital admission bureau should be under the sole jurisdiction of the hospital department, which now controls it jointly with the health department, the report stated. If necessary to achieve integrated service, health department clinics should be turned over to the hospital department, except those conducted by the health department to find new cases. Dr. Haven Emerson was chairman of this committee and members were Drs. Foster Murray and James Burns Amberson Jr., Mr. Henry C. Wright and Mr. Godias J. Drolet.

## OHIO

**Promotions at Western Reserve**—Announcement is made by Western Reserve University School of Medicine of the following promotions to associate professorships: Dr. Norman C. Wetzel in pediatrics, Dr. Emerson Megrair, hygiene and bacteriology, Samuel W. Chase, Ph.D., histology and embryology, and O. W. Barlow, Ph.D., pharmacology. The following were promoted to assistant professorships: Dr. Herbert S. Reichle, pathology, Ramon F. Hanzal, Ph.D., pathologic chemistry, Franklin C. Bing, Ph.D., biochemistry, Donald E. Gregg, Ph.D., physiology.

## OREGON

**Personal**—Dr. James M. O'Dell, Salem, has been appointed superintendent of the Eastern Oregon State Tuberculosis Hospital at The Dalles, succeeding Dr. Dewalt Payne, it is reported.—Major Aldine E. Morgan, chief medical officer at the Veterans' Administration Home at Danville, Ill., for several years has been transferred to the home at Roseville, it is reported.

**Society News**—Dr. Max Cutler, Chicago, addressed the Multnomah County Medical Society, Portland, June 30, on recent advances in radiation treatment of cancer.—Speakers at the annual meeting of the Eastern Oregon Medical Society at Pendleton, June 30, included Drs. James Tate Mason, Seattle, on "Carcinoma of the Colon"; Grover C. Bclinger, Salem, "Early Diagnosis of Tuberculosis," and Louis P. Gambee, Portland, "Management of General Peritonitis."

## PENNSYLVANIA

**Fifty Years in Practice**—Twelve physicians received certificates of honor in recognition of fifty years or more in the practice of medicine at the annual meeting of the Ninth Council District of the Medical Society of Pennsylvania at the Polk State School July 27. An award was made posthumously to the late Dr. Jacob P. Strayer, Oil City, who died recently, and presented to his daughter. Those who received certificates were Drs. William W. Leech and Thomas James Henry, Apollo; Joseph D. Orr, Leechburg; John Thomas Deemar, Kittanning; Edwin N. B. Mershon, Saxonburg; John T. Rimer, Clarion; John F. Summerville, Monroe; David Lewis McAninch, Lamartine; William F. Beyer and Sylvester S. Hamilton, Punxsutawney; Calvin M. Wilson, Franklin; and Spencer M. Free, Dubois.

## Philadelphia

**Camp for Diabetic Children**—The Philadelphia Metabolic Association has established a free camp for children between the ages of 5 and 16 at Blue Grass Lodge, Bustleton. Thirty-two children were to be accommodated from August 27 to September 8. The Children's Country Week Association provides the camp and food, and the association arranges personnel and other details. The new association is made up of physicians, nurses, social workers, dietitians and interested laymen who wish to improve treatment, standardize records, organize diabetic departments in hospitals, disseminate knowledge about the disease and protect the patient from inadequate treatment, nostrums and expensive and worthless food substitutes.

## RHODE ISLAND

**Personal**—Dr. William O. Rice has been appointed superintendent of Rhode Island Hospital to succeed Dr. John M. Peters, who retired January 1. Dr. Rice, who has been acting superintendent in the interim, had served as assistant superintendent since 1910.—Dr. Virgil H. Danford has recently been promoted to the superintendency of Rhode Island State Sanatorium, Wallum Lake.

## SOUTH CAROLINA

**Society News**—Drs. Thomas A. Pitts and Nathaniel B. Heyward, Columbia, among others, addressed the Second District Medical Society, Batesburg, July 31, on "Factors Influencing Gastric Function" and "Gallbladder Complications of Typhoid," respectively.—Dr. Hal M. Davison, Atlanta, addressed the Spartanburg Medical Society, July 30, on hyperpyrexia.—Dr. Edward A. Looper, Baltimore, addressed the Columbia Medical Society, June 11, on diagnosis and treatment of diseases of the larynx, trachea and bronchi.

## TENNESSEE

**Personal**—Dr. William H. McMillan, Erin, was the guest of honor recently at a dinner celebrating his seventy-fifth birthday.—Dr. Russell B. Howard, Murfreesboro, has been appointed health officer of Carter County.

**Health at Memphis**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended August 18 indicate that the highest mortality rate (20) appeared for Memphis and the rate for the group of cities as a whole, 9.9. The mortality rate for Memphis for the corresponding week of 1933 was 14.6 and for the group of cities, 9. The annual rate for eighty-six cities for the thirty-three weeks of 1934 was 11.7, as against a rate of 11.1 for the corresponding period of 1933. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

## WASHINGTON

**Personal**—Dr. Harry H. Dutton has been appointed superintendent of Northern State Hospital, Sedro Woolley, succeeding Dr. Edward C. Ruge.—Dr. Albert S. McCown, Seattle, has been appointed in charge of the child welfare department of the state board of health.

**State Medical Meeting at Spokane**—The Washington State Medical Association will hold its annual session at Spokane, September 10-12, at the Davenport Hotel. The first day will be devoted to the annual golf tournament and the second and third to the scientific and business sessions. The scientific program is as follows:

- Dr. William D. Stroud, Philadelphia, Coronary Disease, Digitalis in the Treatment of Cardiovascular Disease
- Dr. Verne C. Hunt, Los Angeles, Operability of Carcinoma of the Breast: Applicability of Certain Surgical Procedures for Duodenal and Gastric Ulcer
- Dr. Fred W. Bailey, St. Louis, Reduction of Mortality in Appendicitis
- Dr. Brien T. King, Seattle, Etiology of Heart Disease
- Dr. Eugene W. Rocky, Portland, Low Back Pain: Differential Diagnosis and Treatment
- Dr. Paul G. Flothow, Seattle, Treatment of Severe Constipation by Physiologic Surgical Relief
- Dr. Roger Anderson, Seattle, Fractures of the Patella Treated by an Ambulatory Method
- Dr. Sam L. Caldwell, Everett, Retrocecal Appendicitis and Complications
- Dr. Oscar S. Proctor, Seattle, Surgical Treatment of Pulmonary Tuberculosis
- Dr. Homer J. Davidson, Seattle, The Economic Problem of the Physicians of Washington
- Dr. Charles B. Ward, Seattle, Treatment of Malignancies of the Head and Neck
- Dr. Joseph Lynch, Spokane, Diagnosis of Brain Tumor

A public meeting will be held Monday evening, September 10, with the following program:

- Dr. J. Tate Mason, Seattle, Hospitals and the Public
- Dr. Donald V. Trueblood, Seattle, What the Public Should Know About Cancer
- Dr. Stroud, What the Community Should Know About Heart Disease
- Dr. Hunt, Scientific Medicine in Relation to Society
- Dr. Bailey, What You Can Do to Help Your Doctor in Treatment of Appendicitis

## WISCONSIN

**Personal**—Edwin B. Fred, Ph.D., professor of agricultural bacteriology at the University of Wisconsin, has been appointed dean of the graduate school, succeeding Charles S. Schlichter, Sc.D., who retired.

**Society News**—Dr. T. J. O'Leary, Superior, addressed the Barron-Washburn-Sawyer-Burnett Counties Medical Society, June 10, at Rice Lake, on acute diseases of the gallbladder.—Drs. Nelson M. Percy and David S. Beilin, Chicago, addressed the Rock County Medical Society, Beloit, June 26, on "Surgery of Gastric and Duodenal Ulcers and Cancer of the Stomach" and "Analysis of 1,000 Consecutive X-Ray Examinations of the Stomach from the Clinical and Roentgenologic Viewpoints," respectively.—Jacob M. Essenberg, Ph.D., Chicago, made an address on "Embryology of the Ner-

vous System" before the Milwaukee Neuro-Psychiatric Society, June 28 — Members of the Trempealeau-Jackson-Buffalo Counties Medical Society spent July 27 cruising on the Mississippi aboard Dr William J Mayo's yacht, the *North Star* Sixty-three persons were in the party

### GENERAL

**Interchamber Health Contest**—Announcement is made of the sixth interchamber city health conservation contest by the U S Chamber of Commerce, Washington, D C, in cooperation with the American Public Health Association The purpose of this year's contest is to interest the business man in public health and assist in the intelligent fostering and promotion of sound public health practices The fact finding schedules on which the contest is based should be returned to Washington before March 1, 1935

**Society News**—The Pacific Coast Oto-Ophthalmological Society at its annual meeting in Butte, Mont, July 17, elected the following officers Drs Frank B Kistner, Portland, president, Spencer S Howe, Bellingham, Wash, and Casper W Pond, Pocatello, Idaho, vice presidents, and Frederick C Cordes, San Francisco, secretary The 1935 meeting will be held in Portland—Dr Charles T Sweeney, Medford, Ore, was chosen president elect of the Pacific Northwest Medical Association at the recent annual meeting in Salt Lake City, Dr George A Dowling, Seattle, became president and Dr Frederick Epplen, Seattle, was elected secretary-treasurer —Dr Edward Jackson, Denver, was elected president of the Western Ophthalmological Society at the meeting in Butte, Mont, in July, Dr Will Otto Bell, Seattle, vice president, and Dr Andrew J Browning, Portland, secretary The next meeting will be held in Portland

**Railway Surgeons' Meeting**—The American Association of Railway Surgeons held its annual meeting at the Hotel Stevens, in Chicago, August 20-22, under the presidency of Dr Sterling B Taylor, Columbus Among the speakers were

Dr Harvey Bartle, Philadelphia Syphilis—A Problem in Hazardous Industry  
Dr James A Jackson Jr Madison Wis Open Reduction Treatment of Fractures  
Dr Ralph C Hamill Chicago Mental Influences in Traumatic Situations  
Dr Ralph B Bettmann Chicago Penetrating Wounds of the Chest  
Dr Geza De Takats, Chicago Determination of the Proper Level of Amputation  
Dr Otto Jason Dixon, Kansas City Repair and Restoration of Injured Blood Vessels with Viable Muscle

Dr John Garfield Frost, Chicago, was elected president of the association, Drs William A McMillan, Charleston, W Va, Charles C Stillman, Morganville, Kan, and Michael J Owens, Kansas City, Mo, were elected vice presidents, Dr Louis J Mitchell, Chicago, was reelected secretary

**Meeting of Obstetricians, Gynecologists and Abdominal Surgeons**—The forty-seventh annual meeting of the American Association of Obstetricians Gynecologists and Abdominal Surgeons will be held in White Sulphur Springs, W Va, September 6-8, under the presidency of Dr William Wayne Babcock, Philadelphia Among the speakers will be

Dr Frederick S Wetherell Syracuse N Y, Intractable Dysmenorrhea—Relief by Sympathetic Neurectomy  
Dr Lawrence M Randall Rochester Minn A Standard Test for Measuring the Variability of Blood Pressure  
Dr Frederick H Falls Chicago, A Critical Study of 500 Cases of Eclamptic Toxemia  
Dr Willard R Cooke Galveston Solid Tumors of Mesonephric Origin  
Dr Thomas E Jones Cleveland Ohio Recognition and Treatment of Late Bladder Rectal and Intestinal Complications Following Radiation Treatment of Cancer of the Cervix  
Dr Arthur Stein New York, The Use of Small Dosages of Pituitary Extract in Obstetrics A Review of the Last Twenty Two Years  
Dr Edgar A Vanderveer Albany N Y Nonparasitic Single Retention Cysts of the Liver  
Dr Howard F Kane, Washington D C The Use of Paraldehyde in Obtaining Obstetrical Analgesia and Amnesia

The Joseph Price Oration will be delivered Thursday evening September 6, by Prof Erwin Zweifel, University of Munich, Germany on "Diagnosis of Carcinoma of the Uterus in Its Earliest Stages"

### CANAL ZONE

**Society News**—At a meeting of the Medical Association of the Isthmian Canal Zone, Panama City July 17, speakers were Drs Elbert DeCoursey, "The First Fatal Case of Chagas' Disease on the Isthmus of Panama" Joseph R Darnell, "Nephrosis" Lawrence Getz, "Tuberculosis of the Wrist Joint," and Orville G Brown, "Discharges for Disability The Panama Canal Zone" All are from Ancon

### PHILIPPINE ISLANDS

**Restaurants Padlocked**—Twenty establishments for the preparation or serving of food in Manila were closed during the week preceding July 21 as a result of about twenty-five cases of food poisoning with five deaths, the *New York Times* recently reported Almost all those padlocked are owned by Chinese and serve comparatively cheap food Sanitation and refrigeration in such places are usually ignored Although the sanitary code requires inspection, the inspectors are not well paid and are lax in their duties The correspondent pointed out that such conditions do not exist in Manila's larger restaurants and hotels, which are models of cleanliness

### PUERTO RICO

**Influenza Epidemic**—More than 7,000 cases of influenza have been reported in Puerto Rico, according to the *Chicago Tribune*, August 21 A conference of all public health physicians had been called to deal with the epidemic

### LATIN AMERICA

**Radium Center in Colombia**—The National Radium Institute, with 3 Gm of radium, was opened in Colombia, August 4, with ceremonies at which President Enrique Olaya Herrera officiated—The third Pan-American Anti-Tuberculosis Conference will be held in Montevideo, Uruguay, in November

**Poliomyelitis in Cuba**—The *New York Times* reported, August 17, that Dr Edward C Rosenow, Rochester, Minn, had gone to Havana at the invitation of the Cuban government to assist in fighting an outbreak of poliomyelitis It was said that seventy-three children had died in the last six weeks —A dispatch to the *New York Times* from Lima, Peru, states that 400 children in southern Peru have died of measles and convulsive coughs since May and that 3,000 or more children are still suffering from the epidemic

### FOREIGN

**Clinic Staffed by Blind Technicians**—The National Institute for the Blind, London, has opened a clinic for massage and electrical treatments to be given by blind persons who have qualified as chartered masseurs in the institute's school for blind masseurs All treatments will be given under strict medical supervision The clinic was equipped by Mr William Eichholz as a memorial to his cousin Dr Alfred Eichholz who died Feb 6, 1933 Dr Eichholz was formerly chief medical inspector for the board of education and at the time of his death was a councilor for the institute for the blind The Prince of Wales officially opened the clinic, July 6 and Lord Moynihan made an address

### Deaths in Other Countries

Dr Alfonso Poggi, professor of pathology in the University of Bologna, Italy, for many years, died July 22, according to the *New York Herald Tribune*—Dr Auguste Marie, French psychiatrist, died in Paris, July 29, aged 69, according to press reports

## Government Services

### Evaluation of Serologic Tests for Syphilis

The U S Public Health Service announces that a comparative test of the relative value of serologic procedures for the diagnosis of syphilis is to be made within a few months In cooperation with the American Society of Clinical Pathologists, the Public Health Service will collect specimens of blood from at least 1,000 persons and distribute comparable specimens to the laboratories of serologists who have described an original modification of a complement fixation or precipitation test for the diagnosis of syphilis After all laboratory reports have been submitted by participating serologists, a committee of five members consisting of two specialists in clinical syphilology, two members of the American Society of Clinical Pathologists and one officer of the U S Public Health Service will interpret the results on the basis of clinical observations Collection of specimens will begin about December 1 and a number of serologists will be asked to participate Any serologist desiring to participate will be extended an invitation on presentation of suitable proof as to the originality of his modification of a serologic test A brief description of the plan will be sent to workers who may be interested Correspondence should be addressed to the Surgeon General, U S Public Health Service Washington, D C

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Aug 4, 1934

#### Accidents in Industry

In his annual report, the chief inspector of factories and workshops states that he has been impressed by the number of avoidable accidents. The contempt for machinery, which is responsible for a wholly unnecessary toll of death and disablement, is almost incredible, since its dangerous character has been continuously emphasized from the start of factory inspection. An enormous field is open for education of the kind undertaken by the National Safety First Association, so that those exposed to the risk can be brought to realize that all power driven machinery is dangerous. Remarkable results have been obtained by establishing safety organizations in individual factories. On the other hand in an industrial disease the symptoms may not be immediately apparent and the cause may long remain unsuspected. Thus the existence of asbestosis was for years unrecognized. During the last year several problems have arisen. Investigation of the incidence of silicosis among sand blasters has shown that sandblasting is an extremely dangerous occupation. Fortunately the remedy is at hand in the use of other abrasives.

#### DEATHS DUE TO DIETHYLENE DIOXIDE

A series of deaths due to inhalation of the vapor of diethylene dioxide (dioxan) at an artificial silk works led to an inquiry into the extent to which this substance is in use. The result was negative, but a question of wide importance was raised. There is at present no clear relation between toxicity and chemical constitution, and having regard to the use of new organic compounds as solvents, it would seem to be a valuable safeguard for each to be physiologically tested before being placed on the market for general use. Steps have been taken to have this done.

#### STATISTICS OF ACCIDENTS

At the end of 1933 there were 160 185 factories and 86,851 workshops under inspection—an increase of 2 294 factories and a decrease of 4,008 workshops compared with the preceding year. The number of accidents showed an increase from 106 164 to 113 260 and of fatal accidents from 602 to 688. Two reasons for the increase are given. One is an increase in the number of workers employed. The other is the return to work after long periods of unemployment. Many of the workers are suffering from lack of nourishment and are physically and mentally less alert and more liable to mishap than in normal times.

#### THE EFFECT OF INDUSTRIAL WORK ON FEMALES

There are 1 835,500 women and girls employed in factories, of whom 1,391,400 are over the age of 18. Textile industries employ the largest number (657,600), the manufacture of wearing apparel 313,000, and the food industries 140 700. Women and girls are frequently employed in repetition processes and in operating and tending the lighter machines. The inspector Dr Sibyl Horner, says. Such employment illustrates one of the greatest attributes of the feminine sex—adaptability. This is the solution of the riddle which has provoked so much interest in scientific minds—Why is it that women alone of the industrial groups can bring themselves to the daily performance of monotonous work without losing what one may call for want of a better name interest in life? They do it by a nice balance between attention and detachment—which is in effect a prescription for the prevention of boredom. Boys are not so good at maintaining this nicety of balance and why should they when

their outlook is so different from those of women or even from girls of the same age? As to the effect on the health of industrial employment of women and girls, Dr Horner says that on the beneficial side are the stimulating effects of discipline and interests of factory life, with the higher standard of living of wage earners. Conditions in factories are in many cases better than those in the worker's environment. The food in the canteens is good and varied. Health risks are eliminated or reduced to a minimum and women are excluded by law from certain industries presenting definite health hazards. On the other hand, there are adverse effects. They age quickly. Physical attraction is early attained and quickly lost. The reason given by Dr Horner is that women's work often begins when it nominally ends. The house and dependents make their claim on the woman worker. Her work is never done. But the net result is 'good and getting better'.

#### Intellectual Refugees from the German Persecution

Meetings of experts dealing with the intellectual refugees from the German persecution have been held in London. More than 1,300 scholars have been displaced, of whom more than 600 have emigrated or are likely to leave Germany in the next few months. In addition, between 5,200 and 5,500 professional people have had to emigrate because they lost their positions, while 7,000 students had to leave the universities and other institutions before completing their studies. The committee that met this week forms part of the organization set up by Mr J G McDonald, the high commissioner for refugees from Germany. Dr A E Cohn of the Rockefeller Institute, New York, presided at the meetings, and representatives were present of most of the academic and professional committees set up in the various countries to help in the settlement of the refugees. The salient outcome of the meetings is that, provided sufficient funds are forthcoming, most of the displaced scholars and most of the students can be taken care of and permanent places found for them while given a coordinate effort, under the auspices of the high commissioner, a great many of the professional people may hope to create a new livelihood for themselves. It is expected that by July 1935, 140 scholars will be absorbed by the universities and other institutions of learning, while 150 will have found places in research laboratories. Another 130 can be maintained after July 1935 on grants. Thus, 420 of the emigrant German scholars will by then have been enabled to continue their work. The committee will make every effort to create further research scholarships and to elaborate group research schemes. Following a suggestion of Prof Aage Frns of Copenhagen, the high commissioner was asked to pursue negotiations with various governments to obtain permission for placing a limited number of professional refugees both in and outside Europe. It was felt strongly by the committee that the final liquidation of the problem depended on the attitude of these governments. Each country would have to take only a comparatively small number of academic, professional and student emigrants to assure a new livelihood to all those who were driven out of Germany.

#### The Contrast Between Railway and Road Accidents

The official report for 1933 shows that the number of persons killed on the railways of Great Britain was the lowest for thirty years. Six passengers were killed and 619 were injured in train accidents. The number injured is the highest in five years, but it includes 246 passengers injured as a result of buffer-stop collisions the majority of whom suffered only from shock. Eight cases of train accident were attended by loss of life among railway employees, the total casualties being eleven killed and eighty-one injured. While higher than last year, the total is less than the average for the five year period 1925-1929. In 206 cases of accident at level crossings thirty-nine persons were killed and forty-two injured, including forty-

three pedestrians, of whom thirty were killed. These figures compare favorably with the average of the five year period 1925-1929. In movement accidents—connected with the movement of railway vehicles, exclusive of train accidents—152 were killed and 2,406 injured, which compares favorably with the previous year. In train accidents the liability to death was only one in 262 million passengers carried, and to injury only one in two and one-half million.

The contrast between the safety of the railways and the dangers of the roads is brought out in a letter to the *Times* by the well known writer Mr. St. John Irvine. He points out that the terrible figures of road accidents are accepted as part of the daily routine, but if a train is derailed and several

*Passengers Killed and Injured Annually in Train  
Accidents in Great Britain*

1931	6 691	202 119
1932	6 667	206 450

persons are injured or killed the press is full of heavy headlines and a rigorous inquiry is held. Motorists kill more people in a fortnight than all the railways of Great Britain have killed in seven years. Comparison of the accompanying tables is illuminating.

### Why Cambridge Wins the Boat Race

At the health congress of the Royal Sanitary Institute, Dr. J. A. Nixon, professor of medicine in the University of Bristol, attributed the success of Cambridge in the famous university boat race to recognition of the value of sugar in sustaining physical effort. Cambridge's reputation is scientific and it has a well known school of physiology and therefore should know all about the physiology of effort. Oxford's reputation is classic and literary. It is occupied with a past that knew nothing about calories or metabolism and so loses the boat race. Professor Nixon added that Dr. Somervell, the Everest climber, told him that in high altitudes the climbers lost appetite for everything but sugar.

### C. J. Heath

Mr. C. J. Heath, known all over the world for his mastoid operation, has died at the age of 77. Educated at St. Bartholomew's Hospital, he early showed his delicate manipulative skill by winning prizes for anatomic dissection and by his appointment as prosector at the Royal College of Surgeons. He was attached successively to the Central Throat, Nose and Ear Hospital and to the Throat Hospital, Golden Square, of which at the time of his death he was vice president. His papers on "The Cure of Chronic Suppuration of the Ear Without Removal of the Drum, Ossicles or Loss of Hearing" and "The Prevention of Deafness and Mortality, Which Result from Aural Suppuration," have become classics. His remarkable mechanical ability was shown also outside the field of surgery. An enthusiastic sportsman, he invented a chamberless wild-fowling gun. During the war he designed an antigas helmet of which 20 million were supplied to the British army.

### The Absence of Malaria in France

The fact that malaria is rare in France (other than in the island of Corsica) usually occasions surprise. One finds here *Anopheles maculipennis*, which is the agent in transmitting malaria. There are in France many persons who have previously resided in the colonies and who remain infected for a long time and constitute reservoirs of infection. In spite of the apparently favorable conditions for malaria, the disease is almost never observed in persons who have not resided outside of France. The reservoirs of infection were greatly increased at the close of the war by the return to France of soldiers who had served in the Orient, almost all of them being carriers of *Plasmodium praecox* and *Plasmodium vivax*. Nevertheless only a few cases of infection have been diagnosed near certain camps. This has not always been the case. Formerly malaria was prevalent in many regions of France. Flanders (at the mouth of the Somme and the Seine), the Cotentin Swamp, Basse-Loire, Sologne and the valleys of the Aisne, the Charente, the Gironde, the Rhone and the Camargue. But it has disappeared, except in Corsica. Mr. Emile Roubeaud has devoted many years to a study of this peculiar problem. He has published several articles on the subject in the *Annales de l'Institut Pasteur* and in the *Memoires de la Societe de pathologie exotique*. He discovered that in the Vendee and in other regions in which *Anopheles maculipennis* is still found in abundance the mosquito refuses to attack man and prefers to bite animals. In regions where animals exist in large numbers there is no malaria. Attention had been previously called to this fact. Domestic animals, such as dogs, rabbits, horses, cattle and hogs, seem to constitute for man a protective shield. Roubeaud of the Institut Pasteur, during a recent scientific tour in Corsica, found that large domestic animals were numerous and were allowed almost complete liberty in large areas covered with brush and woods—the hot, dark and close stables, such as the French farmer of the continent usually has, and which are the favorite lurking place of *Anopheles*, being absent. That is the reason why in Corsica the mosquitoes prefer to establish their abode in the dwellings. On account of the moderate temperatures, domestic animals are rarely sheltered at night in closed stables. Roubeaud observed also that *Anopheles* gradually adapts itself to new conditions and develops new species, which prefer to bite animals rather than man. The types that bite man have a much weaker biting apparatus than those that attack animals and finally are eliminated by the more vigorous species. The European of the North has seen malaria disappear because he protects his animals better against the cold and thus invites *Anopheles* to his warm stables. Here is a factor in the prophylaxis of malaria that apparently deserves serious consideration and introduces an additional element in the crusade carried on by the ordinary methods.

### Madame Curie

The death of Madame Curie in a sanatorium of the Alpes de Savoie, at the age of 67, has been announced. Her health had been greatly impaired during the last two years and it is supposed that the constant handling of radioactive substances had induced a grave anemia. Madame Curie was a native of Poland, her maiden name having been Marie Sklodowska. In 1893 she entered as a pupil the laboratory of Pierre Curie and later became his wife. She was his collaborator in his search for the elements of radioactivity, the presence of which was suspected in uranium, the first radioactive metal to which Becquerel called attention. As a result of their combined efforts they succeeded, after experimentation covering four years, in isolating a new metal, which was called "polonium" in honor

Madame Curie's native country, the name being later changed to Radium. After the tragic death of Curie in 1906, Madame Curie continued her researches, first in collaboration with her husband and later with Debierne. With the aid of the latter, she isolated pure radium by electrolysis of its chloride. A special chair was created for her at the Faculté des sciences and she was invited to direct, in association with Professor Curie, the Institut du radium de Paris. Her name was proposed for membership in the Académie des sciences, but she was outdistanced by Branly. In 1922 the Academy of Medicine elected her a member of the Section des membres libres. A number of years ago she made a journey to the United States to receive a gift of radium, which had been offered to her (in the form of a general subscription) for the Curie Institute. One of her most recent studies was on the uses of radon. She has two daughters, one of whom is married to a physician (Dr. Marie Skłodowska-Curie) and is continuing, with the aid of her husband, the researches of her parents on radioactivity, while the other daughter, Eve Curie, has distinguished herself as a pianist and has written several plays.

#### Mastoiditis Caused by *Pneumococcus Mucosus*

Mr. Le Maître, head of the otorhinolaryngologic department of the Hôpital St. Louis, has presented to the Academy of Medicine an outline of the results of a research in otology, of which he is an eminent representative. The point in question is the peculiar role of *Pneumococcus mucosus*, a chain pneumococcus that has been termed "*pneumococcus III*." The cases of mastoiditis caused by *Pneumococcus mucosus* are the gravest of the ear suppurations. They may develop without pain, without fever and when the victim is in good general condition. No clinical sign distinguishes them from ordinary simple otitis. The mastoid is often totally destroyed, and the lesion tends to involve the deeper tissues, producing external pachymeningitis. The occipital and the parietal bones and the zygomatic bone become invaded. All the cases of meningitis observed that were due to *Pneumococcus mucosus* were fatal. The diagnosis can be made only by bacteriologic examination and the signs of mastoiditis due to *Pneumococcus mucosus* are almost entirely of a radiologic nature. Treatment should consist of early and ample mastoidectomy. Serotherapy is ineffective and vaccino-therapy is still on trial. Disinfection of the cavity must be continued as long as *Pneumococcus mucosus* is found.

#### The Surplus of Medical Students

The medical league has just published some interesting figures on the overcrowding of German universities and the academic professions. A curve representing medical study during the past sixty years shows three peaks and three lows. From 1870 to 1880 the number of medical students ranged around 3,500 and in 1890 rose to about 8,700. The number of medical licenses granted annually between 1888 and 1903 ranged between 1,200 and 1,500. This excessive number reacted on the number of medical students, which dropped to 6,400 in the summer of 1906. The number of licenses declined in 1907 to 500. This low figure was the signal for increased interest in medical study, so that the number of medical students rose the following summer to 16,000, which denoted an increase of about 150 per cent over the enrollment for the previous summer. The conditions that obtained during the war caused a further increase up to 22,500 students in 1919. Announcement of this excessive registration acted again as a deterrent, so that in 1925 the number of medical students dropped to about 7,750. A dearth of assistant physicians and the uncritical announce-

ment of the incomes of panel physicians again occasioned an enormous increase of medical students, and particularly of women students, the number in 1933 being five times that of 1914. Table 1 shows the registration for the summer semester of certain years between 1914 and 1933.

TABLE 1—Registration of Medical Students, 1914-1933

Summer Semester	Total Registration	No of Women
1914	16,440	979
1919	22,474	2,237
1925	7,758	1,225
1927	9,663	1,541
1928	11,935	1,934
1929	15,067	2,521
1930	18,088	3,261
1931	21,541	4,078
1932	24,808	4,919
1933	25,264	5,123

The classification of the enrolled medical students according to the number of semesters they have studied (as of the summer semester in 1933) reveals the approximate number of graduates during the next few years.

TABLE 2—Students According to Semesters

No of Semesters of Medical Study of Various Students	Total No of Medical Students with Varying No of Semesters	No of Women Students, with Varying No of Semesters
1	2,935	758
2	621	156
3	4,352	905
4	854	205
5	4,565	979
6	868	167
7	3,251	625
8	743	160
9	3,166	529
10	642	122
11	2,749	478
12	196	24
13	152	8
14 or more	158	1
Unknown	12	1
Totals	25,264	5,123

In explanation of the alternate shifting in the figures, it may be noted that most German gymnasiums (secondary schools) end the school year with the beginning of a summer semester (at Easter) at the university. From these figures it is evident that approximately 4,000 students annually will take the government examination (staatsexamen).

The number of Jewish medical students in the summer semester of 1932 was 1,893, which included 591 women students. In the summer semester of 1933 the total number of Jewish medical students dropped to 916, which included 328 women students. Of the 916 Jewish students, 260 were foreigners (thirty-nine women).

TABLE 3—Number of Licenses to Practice Granted in Recent Fiscal Years

Fiscal Year	Total No of Licensed Graduates	No of Licensed Women Graduates
1922-1923	3,062	347
1923-1924	2,616	351
1924-1925	2,430	315
1925-1926	2,033	255
1926-1927	1,488	229
1927-1928	1,158	181
1928-1929	985	188
1929-1930	1,101	202
1930-1931	1,681	270
1931-1932	1,616	273

The number of licenses for 1934 is estimated at 3,500, for 1935 at 4,000, for 1936 at 4,500, and for 1937 at 4,500. In 1931 the annual number of newly licensed physicians needed was placed at 1,200-1,400, but this figure is considered by many as too high. If an optimistic view is taken (that is, if economic conditions improve), more positions might be needed, but it

is not likely that the total number of new physicians required would exceed 1,500. The hospitals and similar institutions require about 2,000 new assistant physicians annually. Under the present conditions it appears likely that these institutions also will have to deal with an excessive supply of physicians, so that a considerable number of physicians either will have to work as volunteers without a fixed salary or will be forced to serve in "work service camps" or elsewhere. In any event, the number of physicians seeking openings during the next few years will vastly exceed the requirements of the country and the limitations imposed by economic conditions.

#### Panel Physicians and Recent Legislation Pertaining to Aryans and Communists

In the *Reichsarbeitsblatt*, the official organ of the federal ministry of labor, Ministerialrat Dr. Karstedt publishes an interesting article on the application to the panel physicians of recent legislation pertaining to Aryans and communists. A general survey is in order now that, with the exception of from twenty to thirty complaints, still to be settled, the work of excluding certain physicians from panel practice, in accordance with the published regulations of the new regime, has been completed. The records show that on Jan. 1, 1933, there were 35,000 physicians who had been admitted to panel practice in Germany. Just what percentage of this number were non-Aryans is unknown, as it is difficult to secure reliable statistics. For Berlin, fairly exact data are available, as prepared by Dr. Lollke, the new chairman of the Berlin Ärztekammer (chamber of physicians). According to his estimation, the total number of physicians controlled in 1933 by the Berlin Ärztekammer was 6,558. So far as can be ascertained, 47.8 per cent of this number or 3,135, were Aryan, whereas 52.2 per cent, or 3,423, were non-Aryan. In the group of non-Aryans there is a small number of physicians who are married to Jews or whose lineage is doubtful. The total number of physicians registered in Berlin as of Feb. 14, 1934, was 6,203, showing a reduction of 355. Of this number 53 per cent, or 3,289, were Aryan, while 47 per cent, or 2,914, were non-Aryan. Here also physicians with a Jewish spouse are counted among the non-Aryans. During the period from the middle of 1933 to Feb. 14, 1934, 154 Aryans were added to the register and 509 non-Aryans were removed. To be more exact, there were 285 Aryans added and 131 were removed, while forty-three non-Aryans were added and 552 were removed. Although, as will be seen from these figures, the relation of the Aryan to the non-Aryan physicians has been reversed, the total increase of the Aryans amounted to only 2.5 per cent, whereas the total reduction of the non-Aryans represented 8.2 per cent of the total number. Among the panel physicians (*kassenärzte*) in Berlin, which in October 1933 numbered 3,481, Dr. Lollke estimates that there were 40.3 per cent Aryan, or 1,404, and 59.7 per cent non-Aryans, or 2,077. According to the last enumeration (February 1934) the total number of panel physicians (*kassenärzte*) in Berlin was 3,144. 51.6 per cent Aryans, or 1,623, and 48.4 per cent non-Aryans, or 1,521. The number of panel physicians shows therefore a diminution of 337, as compared with a reduction of 355 in the number of physicians in general. It is thus evident that the reduction has affected chiefly the panel physicians.

Dr. Karstedt states that in Berlin a total of 1,144 panel physicians have been excluded. Further information may be obtained from the figures that concern the decisions on complaints by reason of exclusion. The supreme authority in reviewing these complaints was the federal minister of labor. The leagues of the panel physicians had excluded 1,030 physicians by reason of non-Aryan origin, 338 by reason of communistic activities, and nine for various other reasons, or a total of 1,377, most of whom filed objections. First the league

of the physicians of Germany expressed its views in the matter, and then the federal minister of labor decided that 827 physicians should not be admitted, ninety-one physicians being excluded by reason of communistic activities, and that 524 physicians should be retained by reason of having fought at the front in the World War. In twenty-six cases no decision was reached. As communistic activity the ministry of labor interpreted all public or private activity or sufferance that was calculated to aid and abet communistic tendencies, even though the suspected person had not been a member of the communist party or of its affiliated organizations, particularly if he had been a member of the *Verein sozialistischer Aerzte* or of certain *Arbeitsgemeinschaften*, and the like.

On the basis of general observations, it may be assumed that at least half of the excluded physicians filed complaints by reason of unjust decisions. Dr. Karstedt points out emphatically that the provisions of the decree were carried out much more rigorously with respect to the physicians than as regards the attorneys. This is particularly true with reference to the question as to whether the complainant was justified in claiming service at the front during the war.

#### RIO DE JANEIRO

(From Our Regular Correspondent)

July 13, 1934

#### International Center for the Study of Leprosy

The work of installation at the center for the study of leprosy is proceeding rapidly. This institution is being established in accordance with an arrangement between the League of Nations and the Brazilian government with the philanthropic cooperation of Dr. Guilherme Guinle.

Its inauguration recently took place at the office of the secretary of the exterior in the presence of high authorities, of the specialists on the staff of the new institution, and of the representative of the League of Nations, Dr. Etienne Burnet. The preparatory work of the International Center of Leprology has been started. The center is already organized with its complete personnel, having its seat at the Institution Oswaldo Cruz, the director of which is Prof. Carlos Chagas, who is also director of the International Center of Leprology and with the installation of a pavilion especially constructed for this purpose at the Hospital-Colônia of Curupaity, in Jacarepagua, a leprosarium exclusively erected for the sick of the federal district and under the direction of the national department of public health. This new pavilion has two stories with wards for two and four patients and a capacity of fifty patients, large verandas and recreation and lecture rooms. On the first floor are the consultation room and treatment rooms. The noncontagious cases of the disease will be treated in private clinics, leaving the beds in the leprosarium for the isolation of the contagious cases.

In the Hospital-Colônia of Curupaity is the section of clinical and experimental therapeutics. The school of Curupaity owes its importance in the center to the visit made to the colony in 1931 by Professor Nocht, well known German expert, who came to Brazil for the League of Nations subsequent to the original proposition made by Professor Chagas.

#### Dr. Couto is Dead

Dr. Miguel Couto, a great figure in medicine in Brazil, died recently, at the age of 70 years, from angina pectoris. Dr. Couto graduated as a Doctor in Medicine from the Faculty of Medicine of Rio de Janeiro in 1886. As a student he was noted for a devotion to his studies, which became more intense during his professional life. Dr. Couto became substitute professor of propedeutics and clinical medicine in the Faculty of Medicine of Rio de Janeiro in 1898, after making a brilliant competitive discussion with Dr. Almeida Magalhães, who was also a prominent member of the profession. In 1901 he was

appointed head professor of clinical medicine, and he held that position until his death. He was the best known of Brazilian clinicians. Among his books and contributions to periodicals were "Dos espiros nas afecções dos centros nervosos," "Das Gelb Fieber," 300 pages in Nothnagel's Medical Encyclopedia, 1901, and "Lições de Clínica Médica" in three large volumes published in 1916, 1918 and 1933. His studies on yellow fever, cardiocirculatory murmurs, visceral polyesteatosis, beriberi and aphasia are all well known. He was the first in Brazil to use methylene blue in the treatment of malaria. He was elected president of the Academia Nacional de Medicina of Brazil in 1913 and held this position until his death. The Academia Nacional de Medicina of Brazil is the oldest scientific institution of South America. It has existed for 105 years. Dr. Couto was a member of the Academia Brasileira de Letras and of many foreign scientific societies.

#### A Method of Staining Blood for the Diagnosis of Leukemia

Dr. H. Froes presented before the Sociedade Médica dos Hospitais de Bahia a report on a staining method which permits a probable diagnosis of leukemia. He examines macroscopically slides prepared with a thick drop of blood and stained by the method of Cropper-Froes, in which methylene blue is used. This method was reported by Dr. J. A. Froes to local medical societies thirteen years ago. Dr. H. Froes exhibited a number of preparations. One slide was prepared with normal unstained blood, the second and third slides were prepared with normal and leukemic blood, respectively, and stained by the Cropper-Froes method. That of normal blood showed a clear green color, while that of leukemic blood showed an intense blue. With this method the nuclei of the leukocytes are stained by the methylene blue, and since in leukemic blood there is a great number of leukocytes, the thick slide of leukemic blood will acquire an intense color. The method is of value, especially when no microscope is available.

#### ITALY

(From Our Regular Correspondent)

June 15, 1934

#### Regulations Concerning Narcotics

The new regulations concerning narcotics, as published in the *Gazzetta Ufficiale*, provide that penalties in the form of imprisonment for from one to three years and a fine of not less than 1,000 lire (\$84) shall be imposed on any person who grows *Papaver somniferum* secretly, who produces crude opium or who collects or carries on traffic in opium capsules, leaves of coca and/or Indian hemp.

No public or private place may be used for the gathering of persons who indulge in the use of narcotic substances not only the keeper of the place but also the addicts are subject to a fine and/or imprisonment.

Persons authorized to sell narcotics may not dispense them without a medical prescription nor to persons whose identity is unknown. Morphine, diacetylmorphine, cocaine and their derivatives may not be sold other than in the form of an ointment or a solution. The medical prescription must be written with ink or indelible pencil and according to a special form it must contain a general description and the address of the patient, the amount of the dosage written out in full, and directions as to the manner and time of administration.

Practitioners who aid or visit a narcotic addict must notify the authorities within two days or they will be subject to a fine of 2,000 lire (\$168).

#### Academy of the Medical Sciences

The Accademia delle scienze medico chirurgiche met recently in Naples under the chairmanship of Professor Pascale, senator

Pennetti spoke on the relation between splenectomy and carbohydrate and oxalic acid exchange. According to some writers the removal of the spleen increases the tolerance for carbohydrates even to the point of producing permanent hyperglycemia, according to others such tolerance is diminished. The speaker studied in splenectomized animals both carbohydrate and oxalic acid exchange. In experiments on dogs he found a distinct but transitory hyperglycemia, which was usually accompanied by hyperoxaluria of short duration.

Tinazzi discussed, from the experimental point of view, the heterologous neoplastic transplant. In order to improve the outcome of heteroplastic transplants of malignant tumors from rats to mice, and vice versa, he added, to the tumor pulp, blood homologous for the receptive animal and heterologous for the tumor, or vice versa. The carcinomas always gave a negative result but the sarcomas gave some positive results. The best results were secured with the addition of blood homologous for the tumor. Jensen's sarcoma brought about occasionally the formation of a sarcoma in the mouse. The tumors obtained differed histologically somewhat from the original. A study of their metabolism showed that the carbohydrate exchange in their cells is quite similar to that of the sarcoma of the rat and differs from that of the original sarcoma of the mouse. Attempts to transplant to the rabbit and the guinea-pig the rat and mouse tumors, with the addition of blood, always failed. The blood added to the tumor pulp has a prevailing local action and furnishes a favorable condition for the growth and the reproduction of the neoplastic elements at the site of the injection. The active part of the blood in this process is the corpuscles.

Argentino carried out research on the healthy and the cataractous crystalline lens. He sought to discover whether the fluorescence that the normal crystalline lens emits in Wood's light can be attributed to organic or inorganic components and concluded that the phenomenon cannot be assigned wholly to the latter, since the fluorescence is found also in the sections of the organ fixed in aqueous solution of formaldehyde in which certain inorganic salts are dissolved. He holds that the greater fluorescence of the cataractous crystalline lens, in comparison with the normal lens, can be ascribed in part to the larger quantity of its inorganic components. But this hypothesis is not definitive, since the histologic changes that the crystalline lens undergoes in the presence of cataract are manifold.

#### The Gynecologic Convention

A gynecologic convention, which was attended by many specialists, was held recently at Salsomaggiore. Professor Alfieri, director of the Clinica di Milano, was elected president.

Professor Cova, director of the Clinica ginecologica and of the research center for the treatment of female sterility, at the University of Turin, described the principal causes of sterility in women, the many forms of treatment (particularly hormone treatment) that may be applied, and the experimental and practical results secured.

Professor Rossi of Parma spoke on the contributions of radiology in the diagnosis of sterility in women. With the technic proposed it is possible to establish, by means of radiology, monolateral or bilateral closure of the tube and also the precise seat of the obstruction.

#### New Mental Institutes at Genoa

The city of Genoa has reorganized the aid for mental patients by combining the three institutes at Cogoleto, Genova-Quarto and Peverano. The institute at Cogoleto is organized as a hospital village with a large agricultural colony in full activity and an industrial enterprise with various features. Here the reeducation of chronic mental patients who are physically strong and amenable to treatment is undertaken. A series of new buildings has been erected at a cost of 5,000,000 lire (\$420,000).

At Genova-Quarto, in the vicinity of the old psychiatric hospital, a new clinical institute for mental diseases has been erected, with a capacity of 500 beds, which is equipped with scientific laboratories. The expenditures amounted to 10,000,000 lire (\$840,000).

Also a new leprosarium has been erected.

#### Professor Simonetta

Prof. Luigi Simonetta, senator, died at Milan at the age of 73. He devoted himself for many years to scientific research in the Hygienic Institute of the University of Siena. He was elected to membership in many high assemblies, particularly the Consiglio superiore della pubblica istruzione, in which body he was for a long period a representative of the senate. He was well known as a philanthropist, having been president of the Collegio per gli orfani dei sanitari, which institution he brought to a high degree of efficiency, having contributed generously from his private means. He was a member of the Direttorio nazionale del sindacato dei medici and of the Associazione per l'igiene, and likewise a commissioner of the Ordine dei medici della provincia di Roma.

#### The Decompression Treatment of Cerebral Tumors

In a communication to the Accademia dei fisiocratici di Siena, Prof. G. D'Ayala admitted that in a large number of cases the physician must be content with prolonging the life of the patient by relieving the symptoms and the pain, in other cases it is important to overcome the acute phases before resorting to a radical intervention, in still other cases it is necessary to improve the general condition of the patient in order to facilitate removal of the tumor. To accomplish this purpose, it is necessary to make use of ventricular puncture and the administration of hypertonic solutions, and, above all, decompressive craniectomy. Subtemporal decompression is not devoid of danger, nevertheless, of the forty-four patients observed in the speaker's clinic, all survived the operation. In many cases the operative results were significant, in other cases they were negative. The technic commonly employed is that of Cushing.

#### Insurance Against Occupational Diseases

The Italian Association of Legal Medicine held recently a session at the University of Parma to study the medicolegal problems connected with compulsory insurance against occupational diseases. Professor Perrando of Genoa called attention to the need that, in schools dealing especially with matters of social insurance, more attention be given to instruction in legal medicine in keeping with modern demands.

The medicolegal conception of occupational disease was discussed. Of importance was the resolution that insurance against occupational diseases is the first step toward a complete protection of the workmen's income against all the causes that operate to reduce it: accident, disease, unemployment, invalidity and old age. Only such a system of complete insurance would make it possible to give adequate protection in many characteristic cases, as, for example, cases of occupational disease aggravated by accident.

Professor Lattes spoke on the compensability of the consequences of infestation with ancylostomiasis. Of the various diseases covered by law ancylostomiasis is the only one in which there is a need, for prophylactic purposes of medicinal interventions in healthy carriers, before the infestation has produced morbid symptoms. Since insurance covers only syndromes actually produced, it happens that the consequences of disinfestation, which are sometimes fatal, are not covered by an indemnity, although they may be regarded as accidents. This is a serious defect in the law.

Prof. Giuseppe Bianchini, of the University of Bari, presented the results of his notable research on the defense appa-

ratus of the lung in relation to pneumonococcosis. Soon after birth, with the onset of respiration, there is within the pulmonary alveoli a defense system formed of phagocytic cells, designed to check and eliminate particles taken in with the respiration from the outside world. The epithelial lining of the alveolus does not participate, directly or indirectly, in this function, since it must remain ready uninterruptedly, in any event of life, to perform its respiratory function.

Professor Biondi, of the University of Siena, reported the results of research on toxicology in connection with occupational diseases, particularly mercurialism in fur workers and the toxicology of tetra-ethyl lead. Biondi traced the general lines of thought among Italian medicolegalists with reference to insurance against occupational diseases.

#### Academy of Medical Sciences, Palermo

At a meeting of the Accademia delle scienze mediche di Palermo, Dr. Mattina spoke on the changes in the blood sugar in experimental stenosis and occlusion of the choledochus. Not only in occlusions but also in stenosis of the principal biliary duct, hyperglycemia is constantly observed. In the animals in which complete occlusion was produced experimentally, increase of the blood sugar index developed rapidly during the first fifteen to twenty days of experimentation. In the animals in which stenosis was induced, hyperglycemia developed slowly during the first fifteen days following the operation, then increased rapidly up to the thirty-fourth day of experimentation. The highest values of the blood sugar in the dogs with occluded choledochus (fifteenth to twentieth day) were constantly higher than the highest values secured (on the thirty-fifth day) in the dogs in which stenosis was produced. After the days mentioned, a slow and gradual diminution of the blood sugar content was observed. The speaker explained the different behavior of the blood sugar as between occlusion and stenosis of the choledochus by the diversity of the changes in the liver that are produced in the two cases. In occlusion the liver undergoes grave changes from the beginning, and it is no longer capable of storing glycogen. In stenosis the liver lesions are in the beginning milder, and the increase of the blood sugar occurs slowly but with acceleration parallel with the aggravation of the changes.

#### Meeting of Italian Surgical Society

At a session of the Società italiana di chirurgia della bocca, Dr. Francia spoke on immunotransfusion in stomatology, stating that he had resorted to that method in a case of osteomyelitis of the lower jaw, using 200 cc of blood and repeating the treatment three days in succession. The results were favorable. He did not succeed so well in two cases of pyorrhea treated (in addition to the usual methods) with a small transfusion of blood derived from a person convalescing from furunculosis. The speaker held that the method of immunotransfusion is to be regarded as a heroic remedy in certain cases of dental surgery but that it was not destined to come into widespread use.

De Fazio discussed the relation between dental caries and pregnancy. He studied the resistance index and the state of the teeth in pregnancy. The diet and endocrine factors have a great influence on dental trophism. From his examination of eighty pregnant women, De Fazio discovered that in the cases in which there was the highest percentage of decayed teeth the anamnesis revealed also other important factors, namely, disturbances of nutrition, hereditary defects, chronic diseases and endocrine disorders. When such factors did not exist, the caries could usually be traced to a period preceding marriage. The number of cases of dental lesions following marriage were too few to conclude that pregnancy exerts a harmful action on teeth.

## Marriages

PAIGE E. THORNTON, Norfolk, Va., to Miss Marianne E Avery of Watertown, N Y, at Towanda, Pa., June 16

ALEXANDER H STEVENS JR, Farmville, N C, to Miss Vera Naomi Bowen of Wilmington, July 8

ALFRED ABRAHAM KENT JR, Granite Falls, N C, to Miss Lena Evelyn Hellen at Vanceboro, July 19

ROBERT HOUGH JORDAN, Beckley, W Va, to Miss Mary Edith Faulkner of Urbanna, Va., June 30

HARDY H SMITH JR, Fort Smith, Ark., to Mrs Eva Jay Ives Armstrong of New Orleans, June 23

JACOB FEIGENBAUM, Montreal, Que., Canada, to Miss Mina Lee Simon of Brookline, Mass., June 24

MAXWELL GOSSE, Poughkeepsie, N Y, to Miss Ruth Dieffendorf Empe of Baltimore April 7

WILLIAM J ELLIS Covington, Va., to Miss Bessie Virginia Withrow of Clifton Forge, June 8

WILLIAM J REED, Oakland, Calif., to Miss Melba L Evans of Peoria, Ill., in Buffalo, recently

JOHN P THOMAS JR to Miss Thelma Elizabeth Fowler, both of Charleston, S C, recently

GERALD M LANE, Springfield, Ohio, to Miss Mildred Everhart of Mechanicsburg, recently

EDWIN OWEN NIVER to Miss Vivienne Elizabeth Davies, both of Mentor, Ohio, August 1

HAL E FREEMAN, Willard, Mo., to Miss Mildred Irene Real at Louisville, Ky, June 14

WILLIAM SCHOOLFIELD, Orleans, Ind., to Miss Martha Jacobs of Mitchell, June 23

VIRGIL STOVER Grand Rapids, Mich., to Miss Gladys Baribeau of Chicago, June 26

J GORDON RENNIE to Miss Anne Marie Lund, both of Petersburg, Va., June 27

CHARLES BAKER, West Milton, Ohio, to Miss Helen Bradley of Dayton, recently

ORIN QUEAL FLINT to Miss Isabelle Foreman, both of Delhi, N Y, August 18

WALTER STOEFLER to Miss Allene Hoch, both of Indianapolis, recently

## Deaths

Thomas Vanhook Fitzpatrick, Cincinnati, Cincinnati College of Medicine and Surgery, 1875, fellow of the American College of Surgeons, at one time mayor of Norwood, professor of laryngology and otology, at his alma mater, 1889-1903 and dean, 1899-1903, professor of laryngology and otology, Woman's Medical College of Cincinnati, 1891-1895, formerly secretary of the Cincinnati Academy of Medicine, for many years on the staffs of St Mary's and the Good Samaritan hospitals, aged 79, died, June 25, of heart disease

Millard Homer Foster, Battle Creek, Mich., Indiana University School of Medicine, Indianapolis, 1926, member of the Indiana State Medical Association and the American Psychiatric Association, served during the World War on the staff of the Battle Creek Sanitarium, formerly on the staffs of the City, Methodist, Riley and Long hospitals, Indianapolis, aged 38, was killed, July 1, in an automobile accident near Three Rivers

Pinkney Venning Mikell, Columbia, S C, Medical College of the State of South Carolina, Charleston, 1900, member of the South Carolina Medical Association and the American Laryngological Rhinological and Otolological Society, fellow of the American College of Surgeons, on the staffs of the Columbia and South Carolina Baptist hospitals, aged 56, died, July 31, of injuries received in an automobile accident

Peter Duncan MacNaughton ♂ Lieut. Colonel, U S Army, retired, Wenham, Mass., University of Michigan Medical School Ann Arbor, 1892, veteran of the Spanish-American and World wars, entered the medical corps of the U S Army as a major in 1920 and retired with rank of lieutenant colonel in 1931 for disability in line of duty, fellow of the American College of Surgeons, aged 66, died, June 8

Frank L Schum Huntingdon, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1886, member of the Medical Society of the State of Pennsylvania past presi-

dent of the Hunt County Medical Society, for many years county coroner, on the staff of the J C Blair Memorial Hospital, aged 69, died, June 25, of diabetes mellitus and chronic nephritis

Francis Michael O'Gorman ♂ Buffalo, N Y, University of Buffalo School of Medicine, 1899, fellow of the American College of Surgeons, served during the World War, attending surgeon to the Buffalo Hospital of the Sisters of Charity and consulting surgeon to the Deaconess Hospital, aged 56, died, August 9, of cardiovascular kidney disease

Alfred Smith Frasier ♂ Dothan, Ala., University of the South Medical Department, 1905, Vanderbilt University School of Medicine, Nashville, 1906, fellow of the American College of Surgeons, part owner of the Frasier-Elis Hospital, aged 53, died, June 14, of pneumonia

Norman Francis Peacock, Darlington, Ind., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897, member of the Indiana State Medical Association, aged 60, died, July 8, of cardiorenal disease and pulmonary embolism

Charles Christian Biedert ♂ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1897, for many years on the staffs of the Episcopal Hospital and the Kensington Hospital for Women, aged 59, died, July 10, of hypertension and cardiac hypertrophy

Daniel Joseph Monihan ♂ Chester, Pa. Medico-Chirurgical College of Philadelphia, 1907, aged 52, on the staffs of the Taylor Hospital, Ridley Park, and the Fitzgerald Mercy Hospital, Darby, where he died, June 28, following an operation for appendicitis

Jacob P Strayer, Oil City, Pa., Jefferson Medical College of Philadelphia, 1880, member of the Medical Society of the State of Pennsylvania, aged 80, on the staff of the Oil City Hospital, where he died, July 12, of myocarditis and hypertrophy of the prostate

Jefferson Nichol Drennen, Loydsville, Ohio, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1890, member of the Ohio State Medical Association, aged 71, was found dead, June 26, of cardiac decompensation

Max Henry Klaus, Cleveland, Western Reserve University Medical Department, Cleveland 1902, member of the Ohio State Medical Association, aged 54, for many years on the staff of the Lutheran Hospital, where he died, July 15, of septicemia

Charles Oliver Ham, Cleveland, Western Reserve University Medical Department, Cleveland, 1897, member of the Ohio State Medical Association, for many years on the staff of the Lutheran Hospital, aged 64, died, July 11, of heart disease

John Gilmore Owsley, Lily, Ky., Hospital College of Medicine, Louisville, 1904, member of the Kentucky State Medical Association, for many years member of the county board of education, aged 67, died, June 23, of heart disease

Ernest Robert McIntosh, Weston, W Va., Tufts College Medical School, Boston, 1897, member of the West Virginia State Medical Association, on the staff of the General Hospital, aged 59, died, June 2, of carcinoma of the bladder

Richard Rupert Stockard, Columbus Miss., University of Virginia Department of Medicine, Charlottesville, 1868, University of the City of New York Medical Department, 1869, aged 84, died, July 21, at Blacksburg, Va., of myocarditis

John Howard Hall, Sacramento, Calif., Atlanta College of Physicians and Surgeons, 1905, member of the California Medical Association, served during the World War, aged 52, died, July 2, in the Sutter Hospital, of duodenal ulcer

Isaac Thompson McCarty, Delaware, Ohio, Western Reserve University Medical Department, Cleveland, 1897, member of the Ohio State Medical Association, aged 66, died, July 11, of myocarditis, angina pectoris and nephritis

Abraham Pincos Fishman, Providence, R I, Jefferson Medical College of Philadelphia, 1905, aged 53, died, June 24, of pneumonia, as the result of septicemia, following a cut on the hand suffered during an operation on a patient

Levi Y Turner, Daingerfield, Texas, University of Louisville (Ky.) School of Medicine, 1890, member of the State Medical Association of Texas, formerly county health officer, aged 74, died, May 18, in Dallas, of heart disease

Edward Swasey, Worcester, Mass. College of Physicians and Surgeons, Medical Department of Columbia College, 1878, aged 81 was found dead in bed, July 23 at Pleasant Point, Maine of cerebral embolism and arteriosclerosis

John Rodney Lambert, Quincy, Ill., Rush Medical College, Chicago, 1889, University of Pennsylvania School of Medicine, Philadelphia, 1890, aged 66, died, July 15, in St Mary's Hospital, of splenomyelogenous leukemia

Francis Albert Bakeman, Franklin, N H., Dartmouth Medical School, Hanover, 1901, member of the New Hampshire Medical Society, on the staff of the Franklin Hospital, aged 59, died, July 9, of cerebral hemorrhage

Carl Oliver Reed, Albuquerque, N M., Sioux City (Iowa) College of Medicine, 1905, served during the World War, on the staff of the Veterans' Administration Facility, aged 51, died, July 7, of a ruptured left ventricle

George M Sands, Rifle, Colo., Baltimore University School of Medicine, 1896, member of the Colorado State Medical Society, aged 66, died, July 9, as the result of injuries received in an automobile accident last Christmas

William Praytor Cooke, Odenville, Ala., University of the South Medical Department, Sewanee, Tenn., 1900, aged 56, died, June 10, in a hospital at Pell City, of injuries received in an automobile accident

Louis Albert Ivey, Washington, D C., Howard University College of Medicine, Washington, 1925, served during the World War, aged 39, was killed, June 21, in an automobile accident at Spartanburg, S C

Anthony H Vorwerk, Burlington, Iowa, State University of Iowa College of Medicine, Iowa City, 1897, member of the Iowa State Medical Society, aged 60, died suddenly, July 26, of heart disease, at St Louis

Henry Hodges Stearns, New York, New York University Medical College, 1897, ship surgeon for the United Fruit Company, aged 60, died, July 25, of cerebral hemorrhage while aboard the *S S Peten*

Henry Allen Barr, Beaumont, Texas, University of Texas School of Medicine, Galveston, 1896, on the staff of the Beaumont General Hospital, aged 60, was found dead in bed, July 12, of heart disease

Albert Golden Eaddy, Johnsonville, S C., University of the South Medical Department, Sewanee, 1900, president of the Florence County Medical Society, aged 56, died, June 21, of cerebral hemorrhage

George Vredenburg Van Neste, Hopewell, N J., Jefferson Medical College of Philadelphia, 1883, member of the Medical Society of New Jersey, aged 78, died suddenly, May 9, of heart disease

Amandus Max Horn, Chicago, Bennett College of Eclectic Medicine and Surgery, Chicago, 1912, member of the Illinois State Medical Society, aged 66, died, July 24, of arteriosclerosis and myocarditis

Robert A Alton, Lansing, Mich., Detroit College of Medicine and Surgery, 1913, on the staffs of the Edward W Sparrow Hospital and St Lawrence Hospital, aged 43, died, July 16, of pneumonia

John Harrison Blanks, Zion, Ill., University of Tennessee Medical Department, Nashville, 1891, city health officer, aged 68, died July 3, of gangrene of both lower legs and feet and chronic heart disease

Frank Howard Van Dyke, St Paul, Minn., Miami Medical College, Cincinnati, 1886, aged 75, died, June 7, in Rochester, Minn., of carcinoma of the pancreas and bronchopneumonia

Melville M Morrow, New Carlisle, Ohio, Eclectic Medical Institute, Cincinnati, 1885, member of the Ohio State Medical Association, aged 73, died, June 27, of carcinoma of the liver

John Henry O'Connor, Boston, Harvard University Medical School, Boston, 1896, aged 65, died, July 7, in St Elizabeth's Hospital, of chronic myocarditis and rheumatic heart disease

Robert Gordon MacKenzie, Frankfort, Mich., University of Michigan Medical School, Ann Arbor, 1907, formerly mayor of Ann Arbor, aged 52, died, June 8, of heart disease

Thomas Marion McGill, Robbins, Tenn., Tennessee Medical College, Knoxville, 1906, aged 49, died, June 6, in the Knoxville (Tenn.) General Hospital, of cirrhosis of the liver

Jefferson Neal McKnight, Fort Worth, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1879, formerly health officer, aged 82, died, June 26, of heart disease

Jerome Jesse Manchester, Indianapolis, University of Vermont College of Medicine, Burlington, 1890, aged 76, died, June 28, in the City Hospital, of arteriosclerotic heart disease

Frank J A Minnich, St Louis, University of Pennsylvania School of Medicine, Philadelphia, 1873, aged 83, died, June 28, of chronic myocarditis and cerebral hemorrhage

Cicero Butler Patton, Batesville, Ark., University of Louisiana Medical Department, New Orleans, 1872, Civil War veteran, aged 90, died, May 3, of cerebral hemorrhage

Louis N Burleson, Cabarrus, N C., University of Maryland School of Medicine, Baltimore, 1891, aged 66, died, June 24, in the Mercy Hospital, Charlotte, of pneumonia

Archibald McGauhey, Robinson, Kan., University of Louisville (Ky.) School of Medicine, 1893, formerly mayor, aged 63, died, June 13, of carcinoma of the throat

James A Stough, Lagrange, Ind., Cincinnati College of Medicine and Surgery, 1889, aged 72, died, July 10, of chronic myocarditis, nephritis and prostatic hypertrophy

Joseph Gaston Baillie Bulloch, Washington, D C., Medical College of the State of South Carolina, Charleston 1877, aged 82, died, July 4, of arteriosclerosis

Thomas C Ross, Philadelphia, Medico-Chirurgical College of Philadelphia, 1905, member of the Medical Society of the State of Pennsylvania, aged 57, died, June 6

Simon Alexander Krumme, Fond du Lac, Wis., Rush Medical College, Chicago, 1886, aged 69, died, July 17, of pernicious anemia and cardiac decompensation

Charles Le Roy Burke, Glendale, Calif., University Medical College of Kansas City, Mo., 1882, aged 80, died, June 20, of arteriosclerosis and cerebral thrombosis

Judson Arlington Van der Hulse, Akron, Ohio, Ohio Medical University, Columbus, 1899, aged 60, died, July 13, in Asheville, N C., of cerebral embolism

Theodore M Lee, Murrayville, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1908, aged 54, died, March 5, of carcinoma of the throat

J W Johnson, Kingsburg, S C., Baltimore Medical College, 1892, aged 61, died, June 29, in the Saunders Memorial Hospital, Florence, of heart disease

William Claiborne Isom, East St Louis, Ill., St Louis College of Physicians and Surgeons, 1898, aged 62, died, July 8, of cholecystitis and cholelithiasis

Marshall Evans Smith, Richfield Springs, N Y., Dartmouth Medical School, Hanover, N H., 1892, aged 66, died, July 1, of cerebral hemorrhage

Charles Newton Sowers, Benton Harbor, Mich., University of Michigan Medical School, Ann Arbor, 1893, aged 74, died, July 17, of carcinoma

John Marvin Brooks, Pasadena, Calif., University of Wooster Medical Department, Cleveland, 1881, aged 77, died, June 14, of heart disease

Clement Paul LeLasher, New Britain, Conn., Medical School of Maine, Portland, 1920, aged 45, died, July 18, of cerebral hemorrhage

William Omar Vallette, Goshen, Ind., Northwestern University Medical College, Chicago, 1891, aged 69, died, June 1, of heart disease

Winfield S Sharp, St Elmo, Ill., University of Louisville (Ky.) School of Medicine, 1875, aged 85, died, May 31, of myocarditis

Charles William Mackenbach, Cincinnati, Medical College of Ohio, Cincinnati, 1900, aged 65, died, June 7, of carcinoma

Robert Willcox Wallis, Rockdale, Texas, Beaumont Hospital Medical College, St Louis, 1894, aged 61, died, May 5

Miles D Cunningham, Decatur, Ga., Atlanta Medical College, 1893, aged 61, was found dead, July 13, of heart disease

William Franklin Simmons, Kell, Ill., Barnes Medical College, St Louis, 1897, aged 76, died, June 29, of myocarditis

Eugene Krohn, Black River Falls, Wis., Rush Medical College, Chicago, 1889, aged 68, died, July 11, of heart disease

John T Mathews, Omaha, St Louis Medical College, 1881, aged 80, died, June 18, of carcinoma of the colon

William Loraine Jones, Oakland, Calif., Meharry Medical College, Nashville, Tenn., 1909, aged 58, died, May 29

Clarence Clarke Towle, Ojai, Calif., Jefferson Medical College of Philadelphia, 1904, aged 58, died, May 3

Cyrus H Barr, Dwight, Ill., Chicago Medical College, 1882, aged 79, died, July 9, of cerebral hemorrhage

L E Miller, Stanberry, Mo., Ensworth Medical College, St Joseph, 1886, aged 69, died, May 30

## MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

**Sulphoradion**—Sulphoradion Co Brooklyn Composition Essentially a thiocyanate such as sodium thiocyanate an iodide such as potassium iodide and a nitrite such as sodium nitrite with flavoring sugar and water For high blood pressure Fraudulent therapeutic claims—[N J 20877 June 1934]

**Breast Tea**—E C Dietz Co Inc New York Composition Essentially licorice root anise seed coriander fruit althaea root tussilagao leaves and mullein flowers For coughs bronchitis sore throat, etc Fraudulent therapeutic claims—[N J 20881 June 1934]

**Cold Inhalant**—American Pharmaceutical Co New York Composition Essentially volatile oils (about 30 per cent by volume) including menthol and lavender, and 70 per cent of alcohol by volume Misbranded because quantity or proportion of alcohol were not declared—[N J 20885 June 1934]

**Cal Spa Mineral Water**—F A Wiggins Seattle Composition Water containing salts of lime magnesium potassium and sodium including iodide equivalent to not more than 175 grains of potassium iodide per gallon For kidney stomach, skin and pulmonary disorders hay fever rheumatism gout nervousness etc Misbranded because of false declaration of potassium iodide content and because of fraudulent therapeutic claims—[N J 20886 June 1934]

**Felsol**—American Felsol Co Lorain Ohio Composition Essentially synthetic drugs including atropine acetanilide and caffeine an organic iodine compound and plant drugs including lobelia For angina pectoris asthma bronchitis hay fever etc Misbranded because presence and quantity of acetanilide not declared, as required by law and because of fraudulent therapeutic claims—[N J 20887 June 1934]

**Gadoxin**—Gadoxin Co Worcester Mass Composition Pink tablets containing baking soda flavored with wintergreen brown tablets containing potassium iodide cinchophen, small quantities of phenolphthalein guaiac resin and extracts of plant drugs including ginger and a laxative For rheumatism neuritis, lumbago arthritis sciatica etc Fraudulent therapeutic claims—[N J 20889 June 1934]

**Granger Vegetable Tonic**—DeVore Manufacturing Co Columbus Ohio Composition Laxative drugs a bitter drug and licorice with small amounts of iron and ammonium compounds glycerine and water For stomach liver and kidney disorders, etc Fraudulent therapeutic claims—[N J 20891 June 1934]

**Nuran Tablets**—LaSalle Laboratories Detroit Composition In each tablet acetanilide 18 grains aspirin 37 grains and caffeine 0.25 grain For toothache neuritis tonsillitis menstrual pains rheumatism influenza etc Misbranded because acetanilide content wrongly declared and because of fraudulent therapeutic claims—[N J 20892 June 1934]

**Frye's Hydrocarboline Spray Solution**—Geo C Frye Co Portland Maine Composition Essentially liquid petrolatum containing 15 per cent of volatile oils including menthol thymol eucalyptol and winter green For tuberculosis pneumonia bronchitis etc Fraudulent therapeutic claims—[N J 20893 June 1934]

**Tan A Wa Tonic**—Tan A Wa Medicine Co, Inc Columbus Ohio Composition Essentially laxative drugs berberis red pepper and a small amount of salicylate with alcohol and water For liver and kidney disorders and female weakness Fraudulent therapeutic claims—[N J 20894 June 1934]

**Tan A Wa Nervine**—Tan A Wa Medicine Co Inc Columbus Ohio Composition Essentially potassium bromide, ammonium bromide sodium benzoate valerian sugar water and flavoring including vanillin For epilepsy fits nervousness, etc Fraudulent therapeutic claims—[N J 20894 June 1934]

**White Cross Liver Medicine**—American Drug Co Mobile Ala Composition Essentially senna leaves For liver disorders biliousness etc Fraudulent therapeutic claims—[N J 20897 June 1934]

**Marlin Mineral Crystals**—Marlin Mineral Water Co Marlin Texas Composition Essentially Glauber's salt with a small amount of table salt and traces of epsom salt and magnesium carbonate For kidney and bowel disorders rheumatism etc Fraudulent therapeutic claims—[N J 20900 June 1934]

**Warner's Safe Diabetes Remedy**—Warner's Safe Remedies Co Rochester N Y Composition Extracts of plant drugs wintergreen a trace of alkaloids glycerine and water Fraudulent therapeutic claims—[N J 20901 June 1934]

**Blake's Herb Tablets**—International Drug Co Boston Composition Extracts of plant drugs including aloe and red pepper and a mint oil For kidney and liver disorders rheumatism indigestion etc Fraudulent therapeutic claims—[N J 20915 June 1934]

**Life Powder and Universal Preservation Remedy**—Clara Boerner, Paterson N J Composition Essentially powdered plant drugs including senna leaves licorice root and fenugreek seeds For bad blood fever kidney disorders etc Fraudulent therapeutic claims—[N J 20909 June 1934]

**Parkalein**—Philip R Park Laboratories Inc Chicago Composition Essentially plant material containing small quantities of compounds of phosphorus iodine calcium magnesium iron, manganese copper sodium potassium aluminum and sulphur For nervousness, anemia eczema asthma rheumatism female troubles, etc Misbranded because amounts of minerals it contained were misrepresented and because of fraudulent therapeutic claims—[N J 20911 June 1934]

**Lanno Rub**—Lanno Rub Chemical Co Washington D C Composition Essentially 78 per cent of volatile oils such as pine needle oil eucalyptol menthol and camphor with glycerine ammonium soap fats and waxes including lanolin, and a small quantity of borax For hay fever asthma catarrh rheumatism etc Fraudulent therapeutic claims—[N J 20919 June 1934]

**Mentoll**—Mentoll Co Fayetteville Tenn Composition Essentially an oil derived from petroleum such as kerosene containing small amounts of camphor and menthol For catarrh neuralgia sore throat pneumonia asthma etc Not antiseptic Fraudulent therapeutic claims—[N J 20923 June 1934]

**Kola Astler Granulated**—Galha Laboratories Inc New York Composition Essentially sugar (97.3 per cent) and small amounts of plant material, including kola For anemia heart disorders brain fatigue old age etc Fraudulent therapeutic claims—[N J 20925 June 1934]

**Nervotol**—Vitono Medicine Co Los Angeles Composition Essentially compounds of lime sodium potassium hypophosphites small amounts of iron and manganese compounds and quinine sugar alcohol (13.3 per cent by volume) and water For debility, anemia sexual disorders female complaint, etc Fraudulent therapeutic claims—[N J 20927 June 1934]

**Novolek**—Health Research Laboratories Detroit Composition Essentially plant drug extracts including a laxative drug, with baking soda, small amounts of calcium and magnesium compounds with alcohol glycerine sugar and water flavored with peppermint For indigestion kidney and liver disorders rheumatism piles, etc Fraudulent therapeutic claims—[N J 20928 June 1934]

**Cheney's Red Clover Flowers**—G S Cheney Co Inc Boston Composition Essentially red clover flower For blood disorders rheumatism cancer etc Fraudulent therapeutic claims—[N J 20936 June 1934]

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

### DINITROPHENOL AND WEIGHT REDUCTION

**To the Editor**—I am entirely new to the use of sodium dinitrophenol Two women wives of physicians have self administered the drug for the past five and six months with seemingly satisfying results The elder (58 years old) has a coronary heart condition Four times a day she takes with the dinitrophenol 1½ grains (1 Gm) of theophylline, the latter prescribed by Dr George Farr of Minneapolis Of course he knows nothing about the secret dinitrophenol She also self administered 1 tablespoonful of liquid petrolatum or something equally bland every morning before breakfast She assures me that she has carefully checked herself during the entire six months The only discomfort she has suffered are excessive night sweats She is now content with her present weight (150 pounds or 68 kg), a net loss of 29 pounds (13 kg) The younger woman now weighs 120 pounds (54 kg) a loss of 18 pounds (8 kg) Both women are 5 feet 1½ inches (155 cm) tall Both women are always hungry The questions they asked me were Can they entirely discontinue dinitrophenol without regaining fat? How small a dosage is required if any is necessary to maintain their present weight? Will the continued use four times daily, of 1½ grains of sodium dinitrophenol alpha (Sutliff & Case Co Peoria Ill) prove harmful? Anything enlightening will be gratefully received Kindly omit name if printed in THE JOURNAL  
M D Minnesota

**ANSWER**—The weight of an individual, regardless of constitution, endocrine disturbance or medication, must always depend on the proportion between the energy intake in the form of food and the energy expenditure Since the women in question have resorted to dinitrophenol, a means of increasing energy expenditure, in order to lose weight, they have probably not reduced their food intake If this is so, with the cessation of dinitrophenol administration they would revert to their previous status If their food intake was sufficient to make them gain weight before they will gain weight now If their weight was stationary before and they have not increased their food intake, their weights may remain stationary now

If the food intake of these women was and still is excessive, the daily amount of dinitrophenol necessary for continuous use to prevent the regaining of weight depends on the amount of excess calories that are being consumed and can perhaps be

most easily determined by trial and error. Of course it might be possible to estimate the matter with a greater degree of accuracy by determining the energy output (basal metabolism plus allowances for work) and calculating the energy intake from the daily diet.

The possible harmful effects of the continued daily use of dinitrophenol for an indefinite period can only be a matter of opinion at the present state of knowledge. These women are apparently not particularly sensitive to the drug, as many people are. There are reports in the literature to the effect that rats and dogs have been given daily doses of dinitrophenol over periods of weeks and months with no demonstrable harmful effects. On the other hand, there are at least equally reliable reports which claim to have demonstrated histologic damage to liver and kidneys resulting from the use of the same drug. It should also be pointed out that there is as yet no adequate knowledge of the effects of the drug over periods of months or years.

Dinitrophenol is a potent and dangerous drug, and long continued use except from a purely experimental standpoint is probably unjustified.

#### GLYCINE AND EPHEDRINE IN MYASTHENIA GRAVIS

*To the Editor*—For the past ten weeks I have kept a patient with myasthenia gravis on glycine and ephedrine. At present the patient claims to be feeling entirely better. Objectively except for a slight droop of the muscles of one side of the jaw when the patient smiles and a hypertension of 150/90 (which I attributed to the constant use of ephedrine the patient being only 25 years of age) nothing can be found. Would you give advice as to how long the glycine (10 Gm. three times a day) and the ephedrine (three-eighths grain or 0.024 Gm. twice a day) should be continued, and if either is to be cut down on should the glycine because of the great expense it involves perhaps be stopped first? Kindly omit name.

M D New York

**ANSWER**—Most patients with myasthenia gravis have to continue taking glycine indefinitely in five or six doses totaling 30 Gm. daily. If they have had very marked improvement as a result of its use the amount of glycine taken can be gradually reduced. A few patients can get along eventually on a total of 20 Gm. and an occasional patient on even less, after about six months. However, if there is any increase in weakness on reduction of the dose, the full amount should be given again. Ephedrine in doses of 0.008 Gm. (one-eighth grain) is more frequently better than 0.024 Gm. (three-eighths grain), one-eighth grain before breakfast, one or two during the forenoon, one or two during the afternoon and none in the evening, a total dose of between 0.024 and 0.04 Gm. (three-eighths and five-eighths grains) daily. A convenient way to use it is to have the ephedrine sulphate powder dissolved in physiologic solution of sodium chloride so that one eighth grain is contained in a teaspoonful. A general diet should be used and if the muscles of mastication are much involved the meat or other food difficult to chew should be ground up. If there is much difficulty in swallowing, the patient should be taught how to take part of his food by a Rehmann tube through the nose into the stomach. The patient should exercise up to the point of fatigue but never beyond.

#### TREATMENT OF SYPHILIS IN PREGNANCY

*To the Editor*—What procedure should be followed in the prenatal care of a patient two months pregnant whose husband has had a Wassermann plus 3 reaction for seventeen years? The patient had a miscarriage eight years ago after which she received twelve injections of mercury and two injections of arsphenamine from another physician. What the Wassermann reaction was at that time is not known. At present it is negative. The husband received eighteen doses of neoarsphenamine 0.6 Gm. and five injections of a bismuth compound over a period of five months in 1930 but stopped treatment because of weakness. The Wassermann reaction remained unchanged. What type dose and frequency of administration of antisyphilitic drug is recommended for the mother in order to insure a healthy baby? Please omit name.

M D New Jersey

**ANSWER**—Whether or not the patient has evidences of syphilis at present, it is almost certain that she did have the disease some years ago. Undoubtedly the physician who treated her eight years ago for syphilis did so on more grounds than simply one miscarriage. On the basis of this and also the fact that the husband still has a positive Wassermann reaction, it is imperative that the patient be treated throughout her entire pregnancy. This must be done in spite of the fact that the patient herself has a negative Wassermann reaction. It may be advisable to try a Kahn or other test for syphilis on the patient. Likewise a spinal fluid Wassermann test should be made.

Care should be exercised in the selection of the drugs used for pregnant women because of the possible harm to the kidneys especially by mercurial preparations. However, other

drugs are capable of producing disturbances. Thus, the use of arsenic may lead to dermatitis and hepatitis, iodides may produce acne and irritation of the upper respiratory tract, bismuth compounds may produce the metallic line on the gums, and bismuth and mercury compounds may bring about intestinal irritation. Before treatment is begun the patient should have a careful and complete physical examination and it is most essential to examine the urine microscopically as well as macroscopically. A highly satisfactory method of treatment is to give arsphenamine intravenously, followed by mercury injections. The injections should be given in courses of from three to six. From one to three months should elapse between courses. During these intervals mercury should be administered in the form of injections. The patient may safely be given between 2 and 25 Gm. of arsphenamine and she may have thirty-five or more injections of mercury. Practically no untoward reactions should occur from this treatment. Abortion does not often result from the use of arsphenamine. Throughout the course of treatment the urine should be carefully examined at frequent intervals. Gammeltoft reported his experiences in the treatment of 1,290 syphilitic women in his hospital in Copenhagen (*Am J Obst & Gynec* 15:747 [June] 1928). He began his treatment with an initial mercury treatment, either in the form of injections or inunctions, that is, seven inunctions of 3 Gm. Then arsphenamine is given together with the mercury treatment. Four injections of arsphenamine are given at intervals of one week, either arsphenamine in doses increasing from 0.3 to 0.4 Gm. of neoarsphenamine increasing from 0.15 to 0.3 Gm. This treatment takes from six to seven weeks. All treatment is then discontinued for a month. Then the patient is given thirty inunctions of mercury or six injections of mercuric salicylate. In the middle of pregnancy the patient is given another energetic combined treatment with mercury and arsphenamine. From eight to ten injections of arsphenamine are given altogether. Then treatment is discontinued for a month and another course of mercury is given. If labor is not due for another month the mercury treatment is again repeated.

#### PAROXYSMAL AURICULAR FIBRILLATION

*To the Editor*—A farmer aged 55 had the usual childhood diseases and a few attacks of malarial fever. He had influenza in 1918 for three days and recovered. He was in the Spanish American War for two years and in 1899 noted a slight heart attack which lasted only a few seconds. It started by hot flashes and heavy heats for a few seconds, then the heart was very irregular and the pulse fast and thready. At the end of the attack he felt a fullness on each side of the neck as if all the veins in it were distended and there was slight pain. Following these symptoms the heart quieted down and was apparently normal. The patient was superintendent of a coal mine from 1905 to 1930 and since then the attacks have increased in frequency and in length. About six years ago he was advised to stop smoking (cigars being the only form of tobacco used) and drinking coffee which he did for two years with no improvement. He has been given sedatives and aromatic spirit of ammonia and amyl nitrite pearls with no improvement. The attacks continue now at irregular periodic intervals from three to five or seven days elapsing and then two occurring in close succession. The character of the attacks is as stated. During the attacks the patient does not want food or water but following the attack he is both hungry and thirsty. About twenty minutes after the attack begins he has a frequency of urination for about half an hour at five minute intervals and then returns to normal. The bowels are slightly constipated but this condition yields to magnesium magma. Physical examination during an attack revealed normal temperature irregular weak and thready pulse with a deficit blood pressure 100 systolic and 65 diastolic heart normal in size and shape and no murmurs. Between the attacks the pulse is regular 68 to the minute at rest and the blood pressure is 110 systolic 70 diastolic. This is increased slightly with exercise. The remaining physical examination is irrelevant. Blood count and urinalysis give normal results. Please give diagnosis and prognosis suggesting a method of treatment. Please omit name.

M D Kentucky

**ANSWER**—A diagnosis of paroxysmal auricular fibrillation would seem to be the most likely one in this case. There is, of course the possibility of auricular flutter with an irregular degree of block, but because of the infrequent occurrence of flutter as compared to that of fibrillation the former diagnosis is more likely to be correct. The response of the pulse to exercise during the attack would assist in differentiating between the two. With fibrillation the irregularity would remain unchanged or tend to become greater, while with flutter a faster but more regular rhythm might appear. In many instances it is impossible to distinguish between the two without a graphic record. An electrocardiogram taken during the attack should solve the problem.

In either case the prognosis is good unless the new rhythm becomes a permanent one. Under the present conditions, effort should be directed toward the prevention of attacks. Quinine sulphate is probably the most valuable drug in the control of

such arrhythmias. As this drug is a cardiac depressant, some care must be used in its administration, but it would seem that in a sound heart such as this probably is there would be but little danger. It is customary to test the patient for idiosyncrasy to the drug by the intral administration of 0.1 Gm by mouth. If no untoward symptoms appear in the next twenty-four hours, 0.1 Gm three times a day may be given. If the attacks continue, the dose may be increased 0.1 Gm each day, each increase to remain unchanged until it is discovered that the attacks still persist.

A daily dose of 2 Gm of quinine is quite safe with a normal heart. Much larger doses have been given. It is desirable, however, to keep the dose at the lowest possible level that produces the desired result.

In addition to the drug therapy the gastro-intestinal tract and the genito-urinary tract should be carefully examined for pathologic changes that may be responsible for the occurrence of these attacks. It seems unlikely, however, that any serious disorder could have existed for the past thirty-six years without detection.

#### DEFORMITY OF RECTUM WITH PAIN AFTER REPEATED INFECTION

*To the Editor*—I have a patient whose case was diagnosed as rectal neuralgia by a Dallas specialist several years ago. He says that he has continuous pain in the distal portion of the rectum and anal canal as though his bowels should move all the time. He has exacerbations lasting two or three days during which he aches all over and this condition will be followed by periods of comparative relief lasting several weeks to a month or more during which he gains weight and feels fairly well. He is worse during periods of constipation. Some time ago he had a dull pain in the left testicle and along the cord through the inguinal canal. He also is bothered at times by pain in the left posterior part of the muscles of his neck. This was more of the nature of a stiffness than a pain. At times he has dull headaches and pains in the extremities. During exacerbations he has trouble with his stomach consisting of pain in the epigastrium relieved by soda and belching. He says that he does not know whether the rectal trouble causes the stomach trouble or the stomach the rectal trouble. The pain in the epigastrium almost always occurs from one to two hours after meals but sometimes at night. He passes much gas. His present trouble began about five years ago. He had had hemorrhoids for two years and bled occasionally when constipated. About 1925 a penile discharge developed that was diagnosed as gonorrhea. He was working in an oil field as a tool dresser at the time and the diagnosis was made by a doctor who was probably a quack. He had little discharge. While receiving treatment for the gonorrhea he noticed the peculiar feeling in the rectum. He was using a white medicine that caused severe burning and was followed by the desire to defecate. This was later followed by the continuous desire to defecate which is not relieved by defecation. He had hemorrhoids removed in 1932 and had relief for a month. Then he saw a rectal specialist in Dallas in 1933 and the condition was diagnosed as rectal neuralgia. He was given a few rectal treatments with rectal electrodes and this made him worse. Then he went to a clinic, where an ulcer was found. Within a month after leaving the clinic he was worse than before, though he had been much improved. Slight labor makes him nervous and shaky and he tires easily. Last fall he was relieved for several months and gained 10 pounds (4.5 Kg). He has lost most of this again. The entire anal canal and rectum are inflamed the distal portion of the rectum and the region immediately above the internal sphincter being markedly inflamed. No ulcers could be found and no hemorrhoids but several tags. The left side immediately above the internal sphincter was worse but no ulcer was visible. The Wassermann reaction was negative last year. Hemoglobin is 90 per cent. The urine is normal. The blood pressure is 120 systolic 82 diastolic. I will greatly appreciate any suggestions that you may offer and I will try to supply any information you may think desirable. Please do not use my name.

MD Texas

*ANSWER*—It is not unusual for such conditions to develop in patients who have undergone similar experiences. It is doubtful whether they ever recover entirely from the discomforts. The disorder can hardly be called a neuralgia when there is so much to account for the dysfunction and discomfort. The trouble is, no doubt, due to the distortion that has developed during the years the patient has been receiving treatment. Recurrent breaking down of tissue with subsequent healing has produced a deformed, scarred and infected rectal outlet. Contraction may be associated. The inflamed tissues are sensitive and the bowel discharges cause discomfort and urgent desire to defecate.

It is doubtful whether any treatment is curative. The best results are usually obtained by the simplest palliative therapy. The patient should use hot irrigations (not enemas) at a temperature between 105 and 110 F daily following the movement of the bowel. This may be followed by irrigations with witch hazel (undiluted) then phenolated or white petrolatum may be used to lubricate and soothe the anal margins. Such treatment will probably relieve the symptoms a great deal, but this relief may exist only temporarily. The same treatment may be necessary at intervals for an indefinite period.

#### GOLD PREPARATIONS IN SNAKE BITE

*To the Editor*—In *Queries and Minor Notes* in *THE JOURNAL* June 23 page 2130 it says that in snake bites injections of gold and mercury salts are useful. What dose of gold sodium thiosulphate would you use? What salts of mercury are used? What dosage? Also would you use them intramuscularly subcutaneously or intravenously? Please omit name.

MD

*ANSWER*—Experimental results with snake bites have shown that the heavy metals such as gold, mercury or zinc, give better results than the oxidizing agents such as the permanganates. However, to obtain any decisive result the metal in full dose must be injected at the site of the bite before a lethal dose has entered the circulation, i. e., within fifteen minutes of the accident.

Most of the heavy metals used therapeutically are put up in ampules for intramuscular injection, such as gold and sodium thiosulphate, and mercuric salicylate in oil. Many preparations of these and other heavy metals might be available for injection if carried in a first aid package.

The injection should circumscribe the bite both subcutaneously and intramuscularly. The amount of drug injected into the subcutaneous tissues should be well distributed, so that tissue necrosis may not occur. Naturally the technic of injection is important so that the drug may be well distributed and the full dose used. Intravenous injection would not be employed.

Practical use has permitted larger doses than given in most handbooks of materia medica. In a life saving injection some chances might be taken in giving a maximum dose.

Gold sodium thiosulphate has been given for other conditions in doses of from 0.0013 to 0.016 Gm ( $\frac{1}{60}$  to  $\frac{1}{4}$  grain) to children and from 0.02 to 0.04 Gm ( $\frac{1}{3}$  to  $\frac{2}{3}$  grain) to adults by injections. Gold chloride used in full dose of from 10 to 15 drops of a 1 per cent solution has been injected at the site of the snake bite with good results.

#### EXOPHTHALMOS AFTER THYROIDECTOMY

*To the Editor*—A man aged 45, had a thyroidectomy eight years ago for a severe exophthalmic goiter with marked exophthalmos and heart disturbance. He has been well since that time except for a considerable degree of exophthalmos and a rapid heart. Last fall he began to feel poorly to fatigue easily and to lose weight. He is becoming progressively worse. There is no indication of diabetes nephritis or any blood disease and no sign of an obvious malignant condition. His lungs are clear and he has no fever. His heart rate is rapid about 90 per minute. He has a fine tremor and a throbbing apex beat. His wife feels that there is now more exophthalmos than a short while ago. He has a good appetite eating a large amount of food but in spite of this he continues to lose weight. He appears to give off a large amount of body heat and his skin is always hot and the color is good in spite of a slight anemia. In November his basal metabolic rate was normal. Is it possible that he is having a recurrence of his exophthalmic goiter? Will a negative basal metabolic rate if repeated entirely rule this out? How frequent are relapses into hyperthyroidism after thyroidectomy? Will a course of compound solution of iodine be of value diagnostically? How much would you give? Kindly omit name.

MD Michigan

*ANSWER*—Marked exophthalmos, especially if of long standing, rarely recedes to an entirely normal state following subtotal thyroidectomy for exophthalmic goiter, some degree of exophthalmos usually remains. In fact, exophthalmos may persist or indeed first be noted after operative intervention when other manifestations of the disease may appear to be controlled. This is ascribed to damage of the rectus muscles of the eyes by some, and to a sympathetic nervous system effect by others.

The persistence of rapid heart action after thyroidectomy may indicate that the operation was not successful in controlling the disease, or frequently enough it may be an expression of permanent myocardial damage, the effect of long continued hyperthyroidism, which would not be influenced by the operation. Tremor, tachycardia, a hot skin, increased appetite, loss of weight and an increase in exophthalmos, taken together, suggest a continuation of the disease following operation in this instance, even though a single metabolic rate is reported as normal. The test should be repeated.

In general, thyroidectomy by an experienced surgeon during the early months of exophthalmic goiter is effective in stopping the progress of the disease. The surgeon acts on the conception that the thyroid is an essential link in the chain which produces hyperthyroidism. Removal of the greater part of the thyroid will in most instances reduce the metabolic rate and the clinical manifestations roughly in proportion to the amount of thyroid substance removed. This is one of the good therapeutic procedures for the control of a major illness which is available in the field of medicine. It is well known, however, that a subtotal thyroidectomy is not a true cure for

exophthalmic goiter. Certain clinical phenomena such as exophthalmos, tremor or tachycardia, as noted in this patient, may make their first appearance or increase following subtotal thyroidectomy, even though other manifestations may seem to have been controlled.

In the case cited it would appear reasonable to suppose that hyperthyroidism has not been controlled by the surgical procedure and is continuing, that a considerable amount of active thyroid substance remains, and that the condition may respond to further surgical intervention. The administration of compound solution of iodine under careful observation at this time may effect a considerable amelioration of the symptoms. If such a favorable result is observed, that in itself may be taken to indicate that the present symptoms are caused by a continuation of hyperthyroidism and a second operation under iodine control for the removal of thyroid remnants is a logical procedure. From 0.6 to 1 cc of compound solution of iodine three times daily would be adequate and may be given over a period of several weeks, the exact dose is immaterial. However, a permanent control of hyperthyroidism by iodine therapy may not be expected.

#### SCOLIOSIS AND PELVIC TILT WITH PAIN IN RIGHT CALF

*To the Editor*—A man of 72 complains of a neuritic type of pain in the right calf worse on weight bearing. Examination two months ago revealed 4 inches shortening of the left leg with the classic observations and history with onset at the age of 4 of tuberculosis of the left hip (quiescent). General physical examination was otherwise negative save for a moderate compensatory scoliosis of the spine. The patient walks with a cane. Neurologic examination was negative, the urine was normal, the blood Wassermann reaction was negative, the prostate was of normal size and consistency. Roentgen examination revealed two devitalized teeth each somewhat infected. In addition one third molar completely unerupted and upside down was seen with no evidence of infection or crowding seen. One of the dead teeth was extracted immediately the other two weeks ago. The man is still suffering considerable pain. Present treatment consists chiefly of rest in bed with a little acetylsalicylic acid occasionally. An internist who has seen this patient with me and an oral surgeon insist that the third molar should come out admitting that there is no evidence of infection or crowding. The argument presented seems to be impacted teeth often cause trouble. Do you consider the scoliosis as possibly the cause of the pain? Do you believe that a completely unerupted third molar free of infection and alive the removal of which is obviously a major operation should be removed in a man of 72 even if his general health and vascular system are very good? Please omit name. M D Indiana

**ANSWER**—There would seem to be a pelvic tilt in this case. It is not a "compensatory" but a postural scoliosis. The patient should not use a cane but two crutches instead. If the scoliosis is the cause of the pain, it should be relieved considerably by rest in bed. It is well known that, in cases of amputation of one leg, flatfoot develops on the other side frequently. Roentgenograms should be made of the lumbosacral and sacroiliac joints for evidence of infection, such as arthritis or tuberculosis. Foci of infection such as occur in the prostate and genito-urinary tract should be investigated, as well as metabolic disturbances. Spinal cord tumor cannot be ruled out except by careful and minute neurologic examination. The tooth is probably the least important factor at the present time. One would suggest caution in removing the unerupted third molar in a man of 72 years. Rest in bed is recommended, with pelvic and leg strapping later on a removable pelvic support may be worn, and taken off for physical therapy including radiant heat, massage and diathermy. The pelvis must be balanced for sitting and standing postures.

#### POSSIBLE INTERMITTENT CLAUDICATION

*To the Editor*—I have a patient who complains of pain in the calf of the leg on walking any distance. He is a bartender and can stand all day and walk up and down behind a bar without any trouble at all. His arches are normal. His blood picture is negative. He has no varicose veins. I can find nothing to account for such a condition. His cramplike pains are very severe requiring him to sit down after walking any distance from a quarter of a mile up. Please omit name. M D Massachusetts

**ANSWER**—This is evidently a case of so-called intermittent claudication, which is a symptom of a peripheral vascular disturbance and should not be considered a diagnosis.

There is a neurocirculatory element underlying the condition, possibly located in the sympathetic nervous system. The myalgia is secondary. The muscle hypertonicity and the neurocirculatory disturbance create a vicious circle.

Some authorities believe that muscle spasm is on the basis of calcium deficiency. Intermittent claudication is the result of arterial spasms and not really a disease entity but it may

develop in the course of any one of several arterial diseases, such as arteriosclerosis, thrombo-angitis obliterans, traumatic arterial diseases, aneurysms, syphilitic arteritis of the extremities, periarteritis nodosa and acute arteritis.

Special significance is attached to the symptom of intermittent claudication because it may be an early sign of threatening gangrene, which by proper treatment may be prevented or at least postponed. It should be considered a danger signal.

There are some contributing factors, such as excessive use of condiments, overexertion, traumas, infections, exposure to cold and particularly nicotine. It is not so much that these patients are heavy smokers as that they are susceptible to nicotine.

Intermittent claudication is often erroneously diagnosed as flatfoot, neuritis, muscular rheumatism, gout, varicose veins and periostitis.

It is not stated whether the symptoms are unilateral or bilateral, nor is one told whether the dorsalis pedis pulse is palpable. Oscillometer readings should be made.

One of the reasons the patient is able to go on with his work is that there is a frequent change of position and he is able to walk a little and rest a little.

It is impossible to say that there are no varicose veins. One may say that there are no superficial varicose veins, because there is an important group of deep veins which may be dilated without superficial evidence.

In addition to roentgenograms of the legs to demonstrate or rule out arteriosclerosis, the patient should have a careful examination for mechanical defects of the feet, such as flatfoot and a short achilles tendon. A casual glance does not rule out a potential defect.

There are various measures which should be considered for this patient, including discontinuance of tobacco in all forms, ingestion of large amounts of fluid such as Willy Meyer solution and alkaline waters, the electric baker, and diathermy to the lumbar sympathetics.

Postural exercises, recommended by Buerger, Allen and others, are helpful. The use of theobromine sodiumsalicylate 0.3 Gm three times a day is of value in some cases. Intravenous saline solution has been highly recommended.

#### SEVERE CONSTIPATION OR HIRSCHSPRUNG'S DISEASE

*To the Editor*—A boy, aged 5 years, suffered from constipation all his life. No stool was passed without huge doses of purgatives or an enema. The usual symptoms of constipation were present. He urinated frequently and dribbled when excited. He wet the bed every night. He slept poorly. When first seen the entire colon was filled with a lumpy mass. Tumor was considered but the history indicated a loaded colon. Two tablespoonfuls of castor oil every four hours were ordered. Twelve tablespoonfuls were required to empty the bowels. Next day the tumor had disappeared. Urinalysis showed only indican. The tonsils were much enlarged but sore throat was rare. Phimosis with adhesions existed. The hemoglobin was 75. The child had pot belly. Otherwise the examination gave negative results. A laxative diet was outlined with much fat. Regular meals and rest were advised. Exercise, including somersaults twice daily were ordered. Atropine sulphate was prescribed increasing daily to tolerance. A purgative capsule with iron and ammonium citrate three times a day was given. The hemoglobin and kidneys are better but the constipation is not.

C W HARPER M D Kings Mountain N C

**ANSWER**—An obstipation of the degree described in this case is indeed rarely seen. The average adult dose of castor oil is from 15 to 60 cc and a five year old boy weighing in the neighborhood of 40 pounds (18 Kg) certainly would under normal circumstances require no more than one or two tea spoonfuls for adequate evacuation of the bowels. The twelve tablespoonful dose required to move the bowels in this little boy allows one to visualize the degree of his constipation. If the rectum and sphincter are functioning normally he must be suffering from some malformation of the colon. Stenosis and atresia of the large intestine may occur, though these are much less common than in the small bowel. Congenital idiopathic dilatation of the colon, known as congenital megacolon or Hirschsprung's disease, could well be the etiologic basis of the constipation in the case described. This condition may be caused by an increased length of the mesentery, permitting twisting of the intestine with a partial occlusion. It may be due to changes in the nerve endings of the muscle wall, causing a paralysis of a segment of the colon. More frequently the condition is due to a congenital anomaly in the development of the colon and the hypertrophy of this organ may have existed in the fetal intestine before birth. These cases present a history of constipation since birth, increasing in severity with the age of the child. There are instances reported in which no bowel movement has occurred in weeks or even months. In many instances an enema following a prolonged

period of constipation will produce a stool that would fill half a pail. After the passage of such a movement the abdomen becomes flaccid. Cathartics seem to have little or no effect on this condition. Recently it has been thought that there may be a congenital imbalance between the sympathetic and parasympathetic nerves, innervating the colon. This has led to a therapeutic sympathectomy for the relief of the condition. The inferior mesenteric plexus and the sacral plexus have both been sectioned in the relief of this condition and good results have been reported from such procedure. A barium enema is a valuable aid in outlining the colon and would prove of interest in the case here described.

#### BRONCHOPNEUMONIA OR TUBERCULOSIS COMPLICATING MEASLES

To the Editor—Recently I have seen two children, both 5 years of age, who developed pneumonia following measles and died from the pneumonia after from fourteen to twenty days. Neither child after the initial stage of the pneumonia had much elevation in temperature. Both mothers were known to be actively tuberculous and in both instances I have suspected tuberculosis. In one child I had roentgenograms made which could not be definitely labeled tuberculous. What would have been the practicability of a tuberculin test, its value and the advisability of administering it? Neither of these cases seemed to fit into that of just an ordinary bronchopneumonia and I have tried to find discussion on such but have failed.

C E HOLLEMAN M D Winston Salem, N C

ANSWER—Bronchopneumonia and tuberculosis are among the more frequent sequelae of measles. Onset of bronchopneumonia usually takes place a few days after appearance of the rash, though it may occur in the prodromal stages or during convalescence. The usual duration of such pneumonia is from a week to ten days, and the temperature varies with the severity and extent of the pneumonic process. Chronic pneumonia, which runs a protracted course of many months, may follow measles. Measles is also credited with arousing into fresh activity a dormant tuberculosis. During an attack of measles the cutaneous response to a tuberculin test that has previously been positive may become negative, and the test may not become positive again till some time after convalescence. This depression of the tuberculin test during measles was termed anergy by Pirquet. Similarly it is known that the Wassermann reaction in a case associated with measles may become negative during the morbillous eruption and positive again after the measles rash has faded. A positive Widal reaction may become negative during an attack of measles. A depression of the skin response to tuberculin during the acute stage of other infectious diseases also may occur. In the cases under consideration, in which both mothers were known to be actively tuberculous, one would be forced to suspect strongly that the measles in these children had reactivated a dormant tuberculosis. Had a tuberculin test been performed during the acute stage of measles, a negative reaction would have been of little value in aiding the diagnosis. The tuberculin reaction is often depressed in fulminating types of tuberculosis in childhood especially in the late stages of a miliary tuberculosis.

#### EFFECTS OF BRAN ON GASTROINTESTINAL TRACT

To the Editor—One of my patients has asked me the following problem: the answers to which I have been unable to find in my references. Is bran injurious when used in the treatment of constipation other than the spastic type? Has it been necessary in certain cases to resort to surgical measures to relieve obstructions caused by bran? Are there laws regulating the sale of bran products because of these dietary dangers? Please omit name and address.

M D Pennsylvania

ANSWER—Bran can be injurious in any type of constipation. The old textbook division of constipation into spastic and atonic varieties is not justified by the facts, because almost all constipated colons appear to be spastic. Some persons who have constipation with a powerful digestion and no tendency to flatulence can be greatly benefited by the addition of bran or other indigestible material to the diet while patients with a weak digestion and a tendency to flatulence are likely sooner or later to get into trouble on any rough bulky type of food. The frail bowel cannot handle it. Answers to a questionnaire (Alvarez, W C. Opinions of 470 Physicians in Regard to the Advantages and Disadvantages of Using Bran and Roughage. *Minnesota Med* 14 296 [April] 1931) indicated that the medical profession is anything but enthusiastic about bran. Most of the men who answered said that they no longer prescribed it and many warned their patients against its use on account of the indigestion it often produces. This does not mean that the substance is always harmful and should never be prescribed. What it means is that it should be prescribed with discretion

in certain types of cases, and always the patient and the physician should know enough to stop the use of the substance as soon as discomfort appears.

Alvarez reported the case of a woman who began the use of bran and in the succeeding four months went downhill until she was skin and bones. In her attempt to relieve the distress in the bowel, she gave up one food after the other until she was living on little besides bran. It never occurred to her to drop that, because she had been led to believe that it was a wonderful health food. In a few cases, bran or any other indigestible material used for the treatment of constipation will pack and cause more or less intestinal obstruction. Alvarez reported a case in which loops of bowel kinked and narrowed and were bound down to the stump of an amputated uterus because packed solidly with bran so that the patient had to be operated on. In the case reported by Murray B Davis (Intestinal Obstruction from Eating Bran, *THE JOURNAL*, July 4 1931, p 24) there was no mechanical narrowing to account for the intestinal obstruction, which had to be relieved by operation.

Manufacturers should warn buyers that not every one can tolerate the substance and that its use should be stopped the minute it begins to produce indigestion, flatulence and malnutrition.

#### CARBOHYDRATES AND BODY ACIDITY

To the Editor—There seems to be an impression among the public that taking carbohydrates causes an acid condition of the blood, not the physiologic carbonic acid but uric acid and the purine group. Can you tell me what the basis is for this widespread belief and what are all the acids that can be formed from the carbohydrates with the exception of the carbonic acid, if any?

SWITHIN CHANDLER M D Philadelphia

ANSWER—The chief acid that may be formed from carbohydrate in the body is lactic acid. However, the acidosis that may occur from the excessive use of carbohydrate foods is not due to the production of this or any other acid from the sugar. The belief may depend on the fact that most high carbohydrate foods of the artificial and refined types are lacking in the basic elements. These basic ions, such as sodium, potassium and calcium, are necessary for the neutralization and excretion of the various acid waste products of the body. Hence carbohydrates may be implicated in the occurrence of such an acid state by displacing other necessary food products from the dietary.

#### EFFECTS OF DIATHERMY

To the Editor—Is there any danger in diathermizing a patient for 1,000 hours? This is the number of diathermy hours Dr X of the city of B gave to a patient for his sciatica, three hours a day for a period of almost a year. The following is a copy of Dr X's letter to me:

Will you kindly inform me as to what pathological conditions may occur from diathermy treatments given over an extended period of time in the organs, fluids or other parts of the body, either grossly or microscopically or any functional symptoms? As far as my experience or knowledge goes I am unaware of any such results. Among my patients I have come across some who have taken treatments in the City Hospital of B for more than seventeen years without suffering any apparent ill effects from diathermy (or other modalities). As I am much interested in that question I would greatly appreciate any information to the contrary you can give me as a result of your knowledge and experience. My opinion is that diathermy should not be used indiscriminately. However I have never encountered any pathologic condition caused by the injudicious employment of this modality though I did not come across patients getting such treatment by the thousands. Would you kindly advise in *THE JOURNAL* as to the possible dangers of such heroic diathermy treatments?

JOSEPH ECHTMAN M D New York

ANSWER—Authoritative opinions are agreed that diathermy is a triple edged agency by means of which stimulating, depressing and lethal effects may be evoked depending on such factors as the length of time required for treatment and the intensity of heat produced. This is based on laboratory evidence showing that the degree of heat saturation differs with the size and resistance of tissue, the size of electrodes and the amperage imposed on it. For medical purposes from ten to forty-five minutes is generally sufficient for the heating of hands to the heating of the thorax or pelvis. To extend the treatment beyond that period is of no physiologic value, because of the depressing action that follows. During the latter stage the patient becomes irritable and restless and is covered with perspiration. If treatment is prolonged, the active hyperemia and the systemic fever influence the body function and provoke a depressing effect on the circulatory apparatus, the general metabolism and the chemical constituents of the body. It is known that only selected cases can withstand the effect of hyperpyretic treatment, these requiring a limited number of treatments to produce the effect desired. Prolonged and daily treatments as described are undoubtedly subhyperpyretic in

action, the constant drain or insult of which tends to produce changes in hydrogen ion concentration, the blood volume, the muscle, nerve and circulatory apparatus, and the secretion of the internal organs. Since no such untoward effects are mentioned, it is reasonable to assume that the dosage was below the minimal range required for the relief of symptoms. It is worth reemphasizing that, if diathermy does not offer some relief within the first few treatments, any number of consecutive treatments will not benefit the patient. Further treatments only shatter the faith of the physician in the established physiologic effects of diathermy and tend to make the patient more skeptical as to the value of any portion of physical medicine.

#### INCREASING VISCOSITY OF FECES

*To the Editor*—I am interested in increasing the viscosity of the content of the large intestine. I have thought of bismuth subnitrate, agar agar, psyllium seed and acacia. Please inform me what the efficient doses will be to use and which substances you think best for my purpose. What other substances can I use with the same object? How can I estimate the viscosity of the intestinal content it being known that I can get it through a colic fistula? What method would you suggest for its measurement? Can you give me some references concerning this problem? Please omit name.

M D, Maryland

**ANSWER**—Apparently the inquirer is interested in drying up and making more viscid the feces coming through a colostomy. In such cases the addition of bulk producers, such as agar, psyllium seed and acacia, would only add to the patient's distress. The feces might be more viscid but they would also be more voluminous and their escape harder to control. Bergen, whose experience in the care of colostomies is large, finds it most helpful to dry the feces with powders such as bismuth subnitrate, tribasic calcium phosphate and kaolin. His favorite is bismuth subnitrate, in heaping teaspoonful doses three times a day. He has not had any trouble with nitrite poisoning. At times, when the stools become too soft, it is necessary to give, in addition, an occasional teaspoonful of camphorated tincture of opium. The use of fluids should be restricted and it would probably help to take only two meals a day. A diet for patients with colostomy is described in an article by Bergen and Victor (*Diet in Intestinal Disorders*, *THE JOURNAL*, July 18, 1931, p. 151).

#### ANTISEPTICS IN SINUSES

*To the Editor*—Please inform me as to the best antiseptics for irrigation and instillation in chronic maxillary sinusitis the infecting organism being of the mixed respiratory variety. Please omit name and address.

M D California

**ANSWER**—It is doubtful whether the use of antiseptics for irrigation or instillation in cases of chronic maxillary sinusitis has any definite or lasting effect. If concentrated solutions of germicides are employed, probably more damage ensues to the ciliated epithelium of the mucosa than to the offending bacteria. However, the use of dilute tincture of iodine or silver nitrate solution, one of the organic silver preparations or one of the organic mercurials, may give temporary relief, especially in acute exacerbations. But when the antral mucosa shows polypoidal changes, no irrigations will avail. Proper drainage is essential and if this does not suffice, some form of radical operation is often indicated in chronic maxillary sinusitis.

#### CHRONIC PERITONITIS AND PERIHEPATITIS— CONCATO AND PICK DISEASE

*To the Editor*—My question to you is prompted by an argument that arose during one of our staff meetings between Dr. A and Dr. B. Dr. A contends that Concato's and Pick's diseases are absolutely identical and that the terms may be used synonymously. Dr. B contends that this is not so, that while the two diseases closely resemble each other in clinical and pathologic manifestations they are two separate disease entities. It being his opinion that Pick's disease begins as a pericarditis whereas Concato's disease does not necessarily begin with pericardial involvement and frequently the etiology of it is tuberculosis. A number of local pathologists have sidestepped the question as to whether the two diseases are identical.

PAUL MURPHY, M D, Koch Mo

**ANSWER**—There is much confusion in the literature in regard to the group of conditions described under the general terms of chronic peritonitis and perihepatitis. Adams uses the term Concato's disease as a synonym for chronic multiserositis or polyorrhomenitis and calls it a "form of chronic mediastinal inflammation which is of a steadily progressive character." It may begin, according to Adams, either as a perihepatitis extending to the mediastinum by the lymphatics involving in its course the right pleura, or as a pericarditis. The adhesions produced are numerous and dense. The newly formed fibrous tissue may undergo hyaline changes so that a substance of

pearly white character and cartilaginous appearance is produced. This frequently is formed on the surface of the viscera, particularly the liver, spleen, lungs and heart. In regard to the liver, the term applied by Curshmann was "zuckerguss leber."

Pick in 1896 described a group of cases under the title of pericarditic pseudocirrhosis of the liver, occurring in young persons with latent adherent pericarditis and ascites. As the result of the chronic progressive inflammatory process the pericardium became thickened and fibrosed, and constricting bands caused obstruction to the vena cava with resultant engorgement of the hepatic veins and the liver, which in turn became fibrotic and ascites followed. This was the predominant feature. Peritoneal involvement was thought to be a minor part of the picture, the result of possible direct extension of inflammation from the pericardium.

Both of these descriptions exclude tuberculosis. If these conditions are not identical, they are nearly so, and probably represent a syndrome rather than a definite disease entity. The condition is not particularly unusual and was first described in 1847 by Van Deen. Since then many observers have commented on various features of the conditions, including Curshmann, Nicholls and Kelly. The apparent variation in the evolution of the disease has led to the confusion of terms applied, as well as the point of view of the observer. The pathologic and clinical features are in the main essentially the same regardless of the term applied. In addition to those of Pick and Curshmann, chronic hyperplastic perihepatitis, chronic deforming perihepatitis, capsular cirrhosis of the liver, multiple serositis, polyserositis, and multiple progressive hyalo serositis have been used by various other authors.

#### INSULIN IN CARCINOMA OF TONSIL

*To the Editor*—I have a patient a man, aged 67 with moderately advanced carcinoma of the left tonsil and marked involvement of the cervical lymph nodes. Of course, the condition is inoperable and not amenable to irradiation. A consultant has advised the hypodermic injection of 4 units of insulin daily, stating that he has seen marked shrinkage of the growth in similar cases by such treatment. I have never heard of this mode of treatment. Will you kindly advise me as to whether or not there is any evidence to support the contention of the consultant? Would you advise such treatment? If so should injections be given in the growth itself or merely subcutaneously? I will appreciate an early reply as my patient is anxious to begin treatment as early as possible if there is any hope of a palliative result.

M D Florida

**ANSWER**—Dr. S. M. Beale of Sandwich, Mass., recently read a paper before the American Laryngological, Rhinological and Otolological Society at its session in Charleston, S. C., in which he reported a great improvement in a number of cases of carcinoma and recommends highly an injection of from 3 to 4 units of insulin daily. A communication addressed to Dr. Beale, requesting full details as to the method of using insulin, will undoubtedly receive courteous attention. It will, of course, take long and careful study, with a large series of cases as controls, to determine definitely just how far insulin is of value in cases of malignant neoplasm.

#### GASEOUS DISTENTION OF BOWEL

*To the Editor*—A woman about 60 years of age has had four children (the youngest is 25 years old). She never had any sickness except that she was always nervous. She has had hysteria since childhood. The heart, lungs, liver and kidneys all seem normal. About three years ago she noticed that she was troubled with gas after meals. At first an eructation of mild odorless and tasteless gas was noticed. Later she expelled gas by the bowel and also belched. Now her abdomen, especially the lower part, is distended all the time sometimes enough to be painful. She has seen many doctors and she has been given acids by some and alkalis by others. She has been dieted until she is much underweight but nothing has given her any relief from the gas. She sees no difference in her condition when she diets and when she does not. She says that possibly potatoes make her worse but she sees very little difference in other foods.

M C JOHNS, M D, Stuttgart, Ark.

**ANSWER**—The data submitted are inadequate to form a basis for any opinion. The statement of nervousness and of the patient having had hysteria since childhood are ambiguous without a description of her symptoms and psychic reactions. The few points mentioned might be referable to a cholecystitis with or without calculi, cathartic colitis, irritable colon or carcinoma of the colon, beginning carcinoma of the pancreas or pancreatitis, some form of gastro-intestinal allergy or many other conditions not necessarily affecting the gastro-intestinal tract. Without a more detailed history, laboratory tests including gastric and stool analyses, cholecystography and a complete roentgenologic study of the gastro-intestinal tract, no definite conclusion can be reached.

# CYSTADENOMA OF OVARY

To the Editor—A woman, aged 27 married five years, without children had an appendectomy seven years ago and scarlet fever six years ago. Last April she noticed a mass in the lower part of the abdomen, which gradually became larger. In July 1933 she was operated on. Operation revealed a large papillomatous cyst with several daughter cysts involving both ovaries. A portion of the left tube was so friable that it crumbled in the surgeon's hand. Both ovaries and the left tube were removed. The diagnosis was bilateral malignancy of both ovaries. Since operation the patient has had the usual symptoms of the surgical menopause but complains of occasional pains in the abdomen like a belly ache. She has gained 10 pounds (4.5 Kg.) since the operation. She has had no high voltage roentgen therapy. What is the prognosis? What is the possible expectancy of life? Is a cure possible with the surgery performed? Please omit name.

M D Michigan

ANSWER—This case is evidently one in which there was a primary papillary cystadenoma of the ovary with malignant degeneration. Even if all the grossly evident ovarian growth was removed there is little hope of a permanent cure without coincident removal of the body of the uterus. Intensive high voltage roentgen therapy is of considerable value.

Ovarian metastases from extension of adenocarcinoma of the body of the uterus may also produce cystic papillary tumors of the ovary. In these cases the prognosis is not as good.

Primary cystic carcinoma of the ovary also resembles cystadenoma of the ovary with malignant degeneration. In these cases the progress is still less favorable.

# EFFECTS OF MERCUROCHROME ON CERVIX

To the Editor—Is there any danger in the application of 2 per cent solution mercurochrome to the cervix about one time weekly in an effort to prevent conception? In the case in mind this has gone on for three years and the cervix is in excellent condition but if this continues do you think there is any likelihood of the mild irritation causing a malignant condition? Please omit name.

M D Louisiana

ANSWER—Mercurochrome in the ordinary strength cannot be compared to iodine as a contraceptive measure, since it has little effect on tissue cells and it is doubtful whether it would inactivate spermatozoa. As this antiseptic in strengths of from 2 to 5 per cent, is commonly used for the treatment of vaginal and cervical irritations, there is no reason for believing that the use as stated would ever cause any type of cervical irritation.

# UNDERDEVELOPMENT AS AN ENDOCRINE MANIFESTATION

To the Editor—I am puzzled as to the diagnosis and treatment of a case. A youth aged 16 5 feet (152 cm) tall and weighing 90 pounds (41 Kg) has immaturely developed secondary sex characteristics: a small penis and no axillary or pubic hair. His mother states that he stopped growing several years ago and since has complained of nervous spells. These come on especially at night and also during the day following severe physical exertion. The spells are acute last about fifteen minutes and are characterized by a feeling of dizziness over the frontal area and occasional neuralgic pains over the left frontal and temporal regions. The boy otherwise is in good physical condition and examination of the heart is negative during these attacks. I have given him phenobarbital and anterior pituitary by mouth with no relief. What therapy and methods of diagnosis would you suggest? Would a Wassermann test be indicated? His past history and the family history are grossly negative. Kindly omit name.

M D Ohio

ANSWER—In the history of this case, the essential points of which are the stationary development, the nervous spells with dizziness and pain over the frontal and temporal regions, a thorough neurologic examination would seem indicated, as well as an examination of the eyegrounds. A tumor of the brain involving the hypophysis and causing inactivity of this gland might account for the stunted growth and retarded sexual development. The side effects of a tumor causing atrophy of the hypophysis would be manifested by an increased pressure on the optic tracts causing narrowing of the field of vision, choked optic disk, retinal changes, headache and dizziness. A roentgenogram of the skull to visualize the sella turcica might be a valuable aid in determining the presence of a hypophyseal tumor. Hypopituitarism, from whatever cause, may result in retardation of growth and sexual development. There are two chief groups of preadolescent hypopituitarism. One type is characterized by a weak, delicate undersized, dwarfed individual with absent secondary sex characteristics. This is the Loran-Levi type. In contrast is the Fröhlich syndrome, in which adiposity to a considerable degree is a marked feature—the so-called dystrophia adiposogenitalis. Hypofunction of other endocrine glands, such as the thyroid and pineal, and, according to some pluriglandular disturbance may cause retardation of growth. With a disturbance in one gland there

may be secondary disturbance in other glands. Congenital syphilis may cause retardation in growth and development and it would therefore be well to perform a Wassermann test. It would be interesting to note whether the testes were descended, as this might have some bearing on the sexual retardation. Recently, treatment of sexual underdevelopment in boys has been attempted with the anterior pituitary-like principle from the urine of pregnancy. This substance seems to be of value as a human gonad activator, and good results have been reported from its use. The dosage and duration of treatment are dependent on the degree of underdevelopment and age of the patient. It has been found that patients who are treated early in adolescence respond more favorably to this substance.

# SCARLET FEVER IMMUNIZATION

To the Editor—How would you suggest that I proceed to desensitize a 5 year old girl for scarlet fever prophylactic doses? She had gradually increased reactions to the first second and third doses of Squibb's scarlet fever antigen and I am loath to proceed until less sensitivity is exhibited. Please omit name and address.

M D, Ohio

ANSWER—It is helpful in such cases to inject 0.2 cc of a 1:1000 solution of epinephrine simultaneously with the dose of toxin, taken up in the same syringe with the toxin. If it has been more than a month since the child received the last dose, it would be best to start over with the first dose. These answers are based on the assumption that by "Squibb's Scarlet Fever Antigen" the writer means the five graduated doses of scarlet fever toxin containing no foreign serum, which are distributed for active immunization against scarlet fever.

# DOSAGE OF DEXTROSE

To the Editor—With all the conflicting dosages of dextrose what is an appropriate dose in grams intravenously per kilogram of body weight? Is it necessary therapeutically to use insulin when giving dextrose? Can insulin be added to the dextrose solution or must it be given separately by hypodermic injection?

SOLOMON J. LEVINE, M.D., Grover, Colo.

ANSWER—It is necessary to distinguish between the appropriate and the maximum dose. Woodyatt and his collaborators have shown that normal adults begin to excrete sugar in the urine when the hourly rate of injection into the vein is above 0.8 Gm per kilogram of body weight. This might constitute a maximum dose. Giving per hour 500 cc of 10 per cent dextrose solution intravenously would be well within the limit but, if continued throughout twenty-four hours, would yield 6,048 calories a day, which is more than double the income required by the resting person. A 60 Kg patient at absolute rest in bed requires a minimum of 1,200 calories a day, which would be furnished by 300 Gm of dextrose, or approximately 0.2 Gm per kilogram of body weight hourly. This might be considered an appropriate maintenance dose of dextrose, which has also the advantage that it can be given at the optimal rate of infusion, which is literally drop by drop. Insulin is not required unless the patient, owing to hypo-insulinism, develops hyperglycemia during such administration. It may be added to the dextrose solution.

# CHANGE OF POSTURE IN DIAGNOSIS OF APPENDICITIS

To the Editor—Is the following diagnostic sign in acute appendicitis in the young and in those with an appendix which is in the pelvis described in standard works on appendicitis? Place the patient so that he or she lies on the face and then palpate over the lower right quadrant of the abdomen. Several recent experiences in some cases that were doubtful as to the proper diagnosis have convinced me that it is a most useful procedure as the tenderness on pressure is markedly accentuated and often brings out a tenderness that is not demonstrated when the patient is lying on his back.

HUBERT B. HAYWOOD, M.D., Raleigh, N.C.

ANSWER—Several writers have emphasized the importance of changing the posture in an effort to determine the presence of tenderness and spasm in suspected appendicitis.

A great many positions are claimed to be helpful, but no mention of the prone position has been seen. No doubt it has been utilized by these physicians, but other positions have been found more helpful.

There is no doubt, from the varied locations in which the appendix may lie, that different positions of the body will influence the amount of tenderness and muscle spasm obtained.

No doubt in all doubtful cases various changes of positions should be made during examination and the prone position may be easily included. This sign may prove helpful.

## PARASYMPATHETIC PHYSIOLOGY

*To the Editor*—What are the chief differences in the physiology of the sympathetic and parasympathetic nervous systems especially in regard to organs or parts not supplied by both? What are the chief differences if any, in the chemistry of activity of smooth and striated muscle? Do all the sphincter muscles of the body have a parasympathetic supply?

J J HORTON M D, Memphis

**ANSWER**—It is suggested that any standard work on physiology be consulted. In general, the parasympathetic system effects contraction of hollow organs with inhibition (relaxation) of the sphincters, whereas the sympathetic activity results in a relaxation of these organs with contraction of the sphincters. All sphincters appear to be supplied with parasympathetic fibers. There are no known differences in the chemistry of activity of smooth and of striated muscle.

## THIOSINAMINE IN ESOPHAGEAL STENOSIS

*To the Editor*—How long and how far may thiosinamine be pushed? I have a child with a stenosis of the esophagus. Dilatation is being employed but the child does very much better under thiosinamine. In other words will it prove a poisonous drug when used over weeks of treatment?

M D Illinois

**ANSWER**—There are possibilities of ill effects from the prolonged use of even small doses of thiosinamine, which may show themselves in modifications of the metabolism, with loss of nitrogen, emaciation and fatty degeneration of the parenchymatous organs, especially the heart and the kidneys. It would be best to give it only in direct connection with the dilations and to watch the effect on general nutrition. As many as fifty injections have been given.

## PATERNITY DETERMINED BY BLOOD GROUPS

*To the Editor*—Mr — is of group III Mrs — is of group IV in the Moss grouping and a girl of 18 is of group III. Mrs — is the girl's mother. What does the grouping indicate as to the relation of Mr —?

R E JENSTROM M D Rapid City S D

**ANSWER**—In scientific medical literature the Moss and Jansky designations of the human blood groups have been replaced by letters O, A, B and AB. O corresponds to Jansky 1 and Moss 4, A to Jansky 2 and Moss 2, B to Jansky 3 and Moss 3 and AB to Jansky 4 and Moss 1. The question concerns what relation there may be between the girl of group B and the man of group B, the mother being of group O. The answer is that as the man and the girl are both of group B, the man may have been the father of the girl so far as their blood grouping goes.

## ELECTIVE SITE FOR VACCINATION AND INJECTION OF SERUM

*To the Editor* In THE JOURNAL July 28 I find the advice to inject alum toxoid subcutaneously at the insertion of the deltoid muscle or in younger children between the shoulder blades. For many years I have almost without exception and at all ages my practice being entirely pediatric made my injections in the upper gluteal region and this because in my judgment it is as insensitive a part of the body as there is and I know no contraindication. My second choice for injection would be the outer aspect of the thigh. I would suggest that if you seriously recommend between the shoulder blades you have some body try it on you once. Then you'll know what I mean.

Even among adults with modern raiment and modern psychology I have had no difficulty for reasons either of practicality or of modesty in using the same location for the occasional parental adult whom I have injected. I simply disinfect the skin with iodine always boil my hypodermic syringe and needle—I mention this because I see other people using a less effective means of sterilization—and never cause an abscess. If there is any objection at all to the location for any reason why it should not be preferred to the insertion of the deltoid or between the shoulder blades I should like to know it.

Recently it was recommended to vaccinate girls on their arms because the modern scar was small. Why make even a small scar on their arms? In some years of practice my location for girls has crawled up from below the knee almost to the crest of the ilium where I put it for cosmetic reasons usually telling the mother with a snicker to keep it under the hatching suit. Even in diaper age babies I have never seen serious trouble and seldom any important irritation.

W D LUDLUM M D Brooklyn

## VOMITING IN INFANCY

*To the Editor*—In Queries and Minor Notes in THE JOURNAL July 21 page 206 a question as to vomiting in infancy is answered. I believe that in this case another possibility should be considered namely congenital diaphragmatic hernia which can cause exactly these symptoms. I recently had occasion to make this diagnosis in the condition in which the patient also vomited on lying down at night. Both roentgen examination and auscultation gave positive signs the mass in the chest and a gurgling sound under the stethoscope.

## Book Notices

**The Medical and Orthopaedic Management of Chronic Arthritis.** By Ralph Pemberton M.S. M.D. F.A.C.P. Professor of Medicine Graduate School of Medicine University of Pennsylvania and Robert B. Osgood A.B. M.D. F.A.C.S. Consulting Surgeon Boston Children's Hospital. Cloth Price \$5. Pp. 403 with 59 illustrations. New York: Macmillan Company, 1934.

This book is presented as a practical exposition of the subject of chronic arthritis for general practitioners, including internists and also for orthopedic surgeons. It sets forth the convictions of the authors that chronic arthritis is largely a preventable and curable disease. Fully aware of existing limitations to knowledge in this field, the authors have eminently proved that there has already accumulated a great fund of principles and facts that must become the common property of all who would understand the problems of these diseases and care for their unhappy victims.

The book is in no particular a second edition of Pemberton's monograph of 1929. It is not quite so much of a delineation of his personal ideas as was the latter, and it presents a broader picture and represents the conjoined opinions of an internist and an orthopedist—a fruitful union—on the cause and treatment of chronic arthritis. It is not an inclusive monograph on the arthritides, however, as the authors have seen fit to exclude any discussion of joint diseases other than those which they term "atrophic arthritis" and "hypertrophic arthritis." Therefore, he who expects to find a handbook on the rheumatic diseases including a clinical discussion and differentiation of fibrositis, rheumatic fever, gouty arthritis, chronic traumatic arthritis and so on will need to refer elsewhere, perhaps to one of the American or the more numerous English handbooks.

The subject matter is divided into fourteen chapters and includes discussions on the history and incidence of chronic arthritis, classification, gross and microscopic pathologic characteristics and the associated physiologic disturbances, and considerations on etiology, symptomatology and treatment. The chapters on therapy concern themselves with general medical principles, adjustments of the major bodily systems by means of physical and mechanical aids, dietetics, and special attention to the gastro-intestinal tract, physical therapy, vaccines, drugs, orthopedic appliances and corrective surgery.

Most of the chapters are concise yet comprehensive, and the wide experience and catholic point of view of the authors are apparent. A perusal of chapter III strikingly shows how meager is the knowledge of the physiology of normal joints. The authors frankly realize that certain of their chapters will as they put it achieve little popularity. If such is the case, chapters IV and V will be most likely to arouse debate. The view held by the authors as to the etiology and treatment of chronic arthritis, repeatedly set forth heretofore, is summarized in these chapters. They believe that some abnormal physiologic process of circulation and alimentation may basically underlie both types of chronic arthritis, atrophic and hypertrophic, and that the joint lesions result from the presence in the blood of

some diffusible irritant with an affinity for joint tissues, perhaps arising from foci of infection, perhaps from some change in the local physiology of the part or from a disturbance of the normal body chemistry other than that caused by specific pathogenic organisms. They frankly do not have much faith in the infectious theory or regard the influence of focal infection as of primary importance, and although they occasionally "pull their punches" by giving brief credit to the (generally unnamed) workers in these fields, they buffer each sentence of praise with many paragraphs concerned with the inadequacies of the theory of infection. The more common arguments in favor of this theory are almost wholly omitted, perhaps on the assumption that they are already well known and that repetition might give them undeserved emphasis. Although they have excluded certain data and statistics that forcefully demand recognition for the theory of infection, they have presented in no little detail those which favor the metabolic theory, but without discussing with equal candor the many objections.

It is with entire propriety that the authors stress their own view that bacteria usually play a secondary and minor part in the pathogeny of chronic arthritis and that a fundamental deviation from normal physiologic function consists probably in a widespread vasoconstriction of smaller blood vessels secondary perhaps to some as yet undetermined fault of alimentation. One may hold in high regard the clinical and physiologic observations of these authors and yet feel that their interpretation of the significance of these observations remains yet to be evaluated and that the present exposition still does not satisfy the questionings of those previously unconvinced. To such as these the authors' deductions on cause and treatment derived from these observations will still seem to be on no more solid ground than those which have engendered the several varieties of the infectious theory.

In chapters IV and V the authors do not seem to hold entirely to that air of impassioned objectivity and judicial detachment so repetitiously enjoined. Nevertheless, the authors' views deserve the openminded consideration of all those interested in these diseases, and while one may not agree with the emphasis placed on alimentation and on circulation and on the remedial value of corrective body exercises and of a low calory diet the foregoing chapters will make him pause and proceed with his own thesis at a more considered pace.

For subsequent revisions of this stimulating textbook a few minor changes are suggested: the inclusion of three or four omitted references in the historical chapter; an improved selection and reproduction of several roentgenograms; the correction of a few errors in fact; the rearrangement of a few paragraphs of inordinate length (from one and a half to two pages); the inclusion of at least some of the bibliography of those "other workers" and, perhaps, a more generous use of photographic illustrations and charts for some of the chapters.

The matured consideration of two of the country's distinguished seniors in this field of medicine, their presentation constitutes a full bodied work, the first comprehensive American monograph devoted exclusively to the two major forms of this vexatious disease group.

**Geographie und Geschichte der Ernährung.** Von Dr. med. K. Hintze. Professor an der Universität Leipzig. Paper. Price 21 marks. Pp. 336. Leipzig: Georg Thieme, 1934.

This is a comprehensive survey of the kinds of food used by mankind in various parts of the world from prehistoric times to the present. Attention is given first to the ancient civilizations of the Egyptians, Babylonians, Hebrews, Greeks and Romans, then to life in Europe over a period of 4000 years, treated in historical periods, viz., prehistorical time, early historical to about 800, Carolingian time, to about 1300, the Middle Ages, and the Modern Era. A brief chapter is devoted to the Far North including northern Canada, Alaska, Lapland, Greenland and polar Asia. The continent of Asia is discussed in terms of the history of food in China, Japan, India and Central Asia, Africa chiefly in terms of its geographic divisions. In the Americas North, Central and South, the discussion is limited to the periods before the entrance of the white man. Finally, Australia and the islands of Melanesia, Polynesia and Micronesia are included in this world review. A bibliography, mostly of German works, is included at the end of each chapter.

To those interested in the history of agriculture this book offers a well organized survey of the whole subject. The main factors are probably familiar to most readers or are available in any good encyclopedia, but the author has culled from many sources interesting details as to food preparation and eating customs in all parts of the world, especially in ancient times, and these lighten the recital of the kinds of food available to the various peoples during the development of agriculture in their respective countries. As a reference book its value would have been enhanced by an index. It would be difficult to trace any food, such as wheat, from age to age or country to country, and although so far as the cereals are concerned this objection has been partly met by a section of the appendix devoted to this subject, it would be difficult to find out when and where any other type of food, fruit or vegetable was first used or how its usage spread from one region to others. In the appendix the old subject of vegetarianism is treated historically and the more unusual topics of earth eating and placenta eating are similarly reviewed. The observations made from time to time in the text regarding the relation of diet to health are not supported by scientific data and can be given little weight. The studies of Krogh on the diet of the Eskimo, of Adolph and of Wu on the Chinese diet, of McCarrison on diets in various parts of India, of Orr and Gilks of certain tribes in South Africa exceed in scientific value any citations regarding nutrition made in this book.

**Radiologic Exploration of the Mucosa of the Gastro Intestinal Tract** By the Cole Collaborators. Lewis Gregory Cole M.D. Robert E. Pound M.D. William Gregory Cole M.D. Russell R. Morse M.D. Courtenay J. Headland M.D. and Ames William Naslund M.D. Cloth. Price \$7.50. Pp. 336 with 262 illustrations. St. Paul & Minneapolis: Bruce Publishing Company, 1934.

As readers are duly warned in the preface, this is not a book on the roentgenologic diagnosis of individual gastrointestinal diseases but a description and analysis of principles on which such diagnosis is based. Accordingly, four broad divisions of the text deal successively with (1) the lumen of the tract viewed in profile, (2) special folds of the mucosa viewed on edge, (3) pliability of the mucosa to peristaltic contraction, and (4) the pattern of the mucosal folds, all as applied to the examination of the esophagus, stomach, duodenal bulb, small bowel and colon.

In recent years continental radiologists, led by Berg and Akerlund have written voluminously on the mucosal relief and its importance in diagnosis. Indeed, this feature has been exploited so energetically as to foster the impression that the method is wholly new. To correct this misconception, American writers have pointed out that the principle is by no means novel for it has been generally employed almost since the beginning of gastro-intestinal roentgenology, and that Berg, expressly disclaiming priority in this field, has given full credit to the pioneer work of the Viennese roentgenologists and the later contributions of Forssell. This protest is ably seconded by the present volume, which states that the method was used as a routine in America as early as 1910. Further, it is stated, articles by Akerlund and Berg would lead one to believe that they employ variations in the mucosal pattern as the foundation for every diagnosis, whereas on investigation it will be found that practically all their diagnoses are based on changes in the luminal contour.

Although most roentgenologists follow Holzknecht and rely primarily on roentgenoscopic examination, the senior Cole has adhered tenaciously to serial roentgenography. Hence the technique described in this volume is essentially roentgenographic and is carried out either by serial roentgenography or by what might be called examination de luxe, roentgenocinematography. Whatever may be the opinion of other roentgenologists as to the comparative merits and practicability of roentgenography and roentgenoscopy, they will concede the general efficiency of the roentgenographic procedure as executed by Cole and his associates.

With its broad pages, clear typing and excellent illustrations the book is typographically attractive. Its contents are never dull, for they faithfully reflect a dynamic personality. Interspersed with the ponderous polysyllables that belong to the roentgenologic ritual are many whimsical and homely but apt similes and many pungent bits of sarcasm.

Not all roentgenologists will accept the contentions here set forth, but their dissent will not in the slightest degree shake the confidence or courage of militant Lewis Gregory Cole. Veterans in this field will not fail to read the book with respectful attention, for they are well aware of Cole's important contribution to the diagnosis of duodenal ulcer and his valiant service to the direct method of diagnosis. New recruits should read it that they may get a broader comprehension of roentgenologic tactics and strategy. Noncombatants, physicians who are not roentgenologists, can read it with profit, for they may at least acquire a realization of the fact that a reliable diagnosis cannot be obtained merely by filling a viscus with barium and "shooting" a single roentgenogram.

**La cholecystectomie sans drainage (cholecystectomie idéale).** Par P. L. Mirizzi professeur titulaire de clinique chirurgicale à la Faculté de médecine de Cordoba (Argentine). Paper. Price 28 francs. Pp. 105, with 71 illustrations. Paris: Masson & Cie 1933.

This discusses the author's experience in a large series of cases in which cholecystectomy without drainage has been used. Approximately half the book is given over to the discussion of this problem, with frequent references to the literature and with a description of his operative technique, which is completely illustrated with excellent two-tone drawings.

The most interesting part of the monograph is on studies in cholecystography made in the course of operations on the biliary tract. Thirty-seven excellent reproductions of roentgenograms taken of the biliary tract at the time of, or shortly after, operation, showing various obstructions, are presented. Iodized oil, injected through the cystic duct at the time of operation, was used as the substance to fill the biliary passages and obtain the roentgenograms. Concise, excellent explanations are given beneath each. A discussion regarding the association of lesions of the pancreas and sphincter of Oddi is instructive and will serve to advance present knowledge and understanding of these less frequent, and yet many times puzzling, lesions the symptoms of which are frequently referred to as the post-cholecystectomy syndrome. Professor Mirizzi's monograph is a contribution to the physiology of the intrahepatic and extrahepatic biliary passages, particularly as altered by disease.

**A Study of Growth and Development. Observations in Successive Years on the Same Children.** By R. M. Fleming. With a Statistical Analysis by W. J. Martin. Medical Research Council Special Report Series No. 190. Paper. Price 1s. 6d. Pp. 85. London: His Majesty's Stationery Office 1933.

This pamphlet is a statistical study of various measurements taken on children from the age of 3 to 18 in a group of mixed Welsh and English ancestry. More than 1,200 children were studied and the unique thing about the author's work is that observations were made on successive years on the same children, whereas most statistical studies have not followed the various children throughout the growth period. The author confirms the observations that growth occurs in at least two major spurts and the well known fact that girls exceed boys in size in the early adolescent period. The statistical analysis also covers pigmentation of the skin, eye color and forehead shape and discusses various physical, physiologic and psychologic characteristics.

**Einige Carcinome und Adenome beim Menschen. Ferner vom Krebs bei Tieren und 'In Vitro'.** Von K. A. Helberg. Paper. Pp. 53 with 2 illustrations. Copenhagen: Levin & Munksgaard. Leipzig: Georg Thieme 1934.

The author develops the theory previously expressed in his "Grundlage der Geschwulstlehre" concerning the development of cancer by purely mechanical strain (including in this inflammation and chemical influences) on tissue. This results in a displacement of the previous activity of the cell to a higher level, which is expressed in an enlargement of the entire cell or some part of it relative to normal dimensions. He admits also certain tissue predisposition that synergizes the external stimulus. He pleads for the abandonment of previous concepts of tumor classification based on the characteristics of the tumor tissue as a whole (i.e., faulty differentiation or forgotten embryonic cells) in favor of one based on actual microscopic measurement. He feels definitely that the cancer cell is a unique thing. To demonstrate his theory further he offers tables having the nuclear length in micromillimeters as one coordinate

and the various tumors graded or classified histologically as the other. It is his opinion that this is superior to the grading by the conventional methods (i. e., uterus as undifferentiated ripe, unripe and middle ripe). The superiority lies not only in advantages from the standpoint of classification but also from that of prognosis and the situation of radiosensitive growths. The tables offered include carcinoma of the uterus, myoma, ovarian and fallopian carcinoma, prostatic carcinoma, and adenoma, seminoma, carcinoma of the stomach and colon, skin carcinoma, tumors of the nasal glands, liver and pancreas. He also discusses certain experimental tumors of mice from the same standpoint. The article must be read in connection with the author's previous work to be of most value and the tables in it warrant more careful study than can be presented in a brief review.

**An Introduction to Practical Bacteriology. A Guide to Bacteriological Laboratory Work.** By T. J. Maclellan M.D. D.P.H. Professor of Bacteriology, University of Edinburgh and J. E. McCartney M.D. D.Sc. Director of Research and Pathological Services, London County Council. Fourth edition. Cloth. Price \$4. Pp. 504 with illustrations. Baltimore: William Wood & Company, 1934.

This is one of the best laboratory manuals in the English language. It is clear, concise, accurate and wonderfully abreast of current knowledge. In this edition one even finds a reference to the St. Louis encephalitis epidemic of 1933. There are few things to which the most carping critic can take exception, but

Page 348. Not all bacteriologists agree that Morgan's bacillus and allied types are responsible for some cases of infantile diarrhea in temperate climates.

Page 371. Tularemia in the United States is not confined to the "Western states" but has been reported from practically every state in the Union and from at least one section of Canada.

Pages 428-429. Recent American work is not given full consideration in the section on typhus fever.

The book as a whole can be given the highest praise.

**Die Typenlehre in der Mikrobiologie. Ihre Grundlagen und ihre Bedeutung für die Epidemiologie, Klinik und Therapie.** Von Prof. Dr. med. et phil. Max Gundel. Paper. Price 8 marks. Pp. 192. Jena: Gustav Fischer, 1934.

The discovery that different "species" of bacteria are not units but consist of a larger or smaller number of "types," each with its own pathologic implications, has had important practical consequences. Biochemical and serologic differences at first sight of minor importance have turned out to be of first class significance. The author of this useful little monograph, himself well known as a student of bacterial types, has brought together most of the well established facts in a clear and compact form. Although often treated rather summarily, as in the discussion of *Bacillus botulinus* (pp. 96 and 97), the material is on the whole dealt with critically and with an expert hand. The sections on streptococcus types are particularly good. The book will be of service to all students of one of the most vexed questions in modern bacteriology.

**Lehrbuch und Atlas der Haut und Geschlechtskrankheiten für Praktische Ärzte und Studierende.** Auf der Grundlage von Prof. Jacob's Atlas der Hautkrankheiten. Textlich vollständig neu bearbeitet von Dr. Karl Zieler, o. B. Professor und Vorstand der Universitäts-Klinik und Poliklinik für Haut und Geschlechtskrankheiten in Würzburg. Band I. Text. Band II. Tafeln. Third edition. Cloth. Price 48 marks per set. Pp. 664. 181 with 512 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1934.

This is a revision of Jacob's well known Atlas of Skin Diseases, with an accompanying text by one of the best known German dermatologists. Volume I gives a brief but complete survey of the field of skin and venereal diseases. In this volume are 168 illustrations chiefly drawings of microscopic preparations and fungi. Volume II contains 342 colored reproductions. The majority of these are of high class and the colors are beautifully brought out. Some, however, have an artificial appearance because they are taken from moulages and lack photographic accuracy. Taken together these two volumes should prove of great value to the student of dermatology and will be found of great assistance in visualizing the appearance of the numerous and varied cutaneous disorders illustrated. The price seems reasonable.

## Medicolegal

**Death Due to Hypersusceptibility to Nupercaine an Accident.**—The defendant insurance company issued a policy to the plaintiff's wife that provided for the payment of a certain benefit if she died from 'accidental bodily injuries

effected solely and independently of all other causes through accidental means." In the course of a tonsillectomy, her physician painted the operative area with nupercaine and injected "the usual amount" of the same drug. While the operation was in progress, his patient collapsed, and died within a few minutes. The surviving husband, as the beneficiary under the policy, sued the insurer for the benefits it had promised to pay. The testimony was to the effect that the attempted removal of the patient's tonsils had nothing to do with her death, that death was due to the administration of nupercaine and the patient's hypersusceptibility to it, and that such hypersusceptibility could not have been known to any practicing physician before the drug was applied and administered. Judgment was given in favor of the beneficiary under the policy, and the insurer appealed to the Supreme Court of Michigan, contending apparently that death was not due to an accidental bodily injury within the meaning of the policy.

"Accidental injuries," said the Supreme Court, have been defined as follows: "Where the effect is not the natural and probable consequence of the means which produce it—an effect which does not ordinarily follow and cannot be reasonably anticipated from the use of the means, or an effect which the actor did not intend to produce, and which he cannot be charged with a design of producing—it is produced by accidental means." 1 C. J., p. 427. The act which here preceded the death of the insured was the administering of the anesthetic to the patient by her physician. As a result thereof, owing to her hypersusceptibility to this drug, an unforeseen, unexpected and unusual occurrence—death—followed. Clearly, the death was caused by accidental means. Judgment in favor of the beneficiary under the policy was affirmed.—*Wheeler v. Title Guaranty & Casualty Co. of America (Mich.)* 251 N. W. 408.

**Malpractice Liability of Physician for Error of Judgment.**—De Groot sued the defendant-physicians for alleged malpractice in the treatment of his fractured leg. A judgment in favor of the patient was reversed by the Supreme Court of Michigan.<sup>1</sup> A second trial resulted in another judgment for the patient, and the defendant-physicians appealed again to the Supreme Court.

The defendants contended that the trial court erred in permitting a lay witness to testify as to the plaintiff's physical condition. One does not have to be an expert witness, said the Supreme Court, to testify to what one sees and knows. An ordinary witness can describe what he sees and can testify concerning the kind of injury or sickness in others whom he has had occasion to consort with, unless it is something out of the common course of general information and experience or unless the question presented involves medical knowledge beyond the ken of ordinary laymen. On the whole, said the Supreme Court, we are satisfied that the trial judge correctly instructed the jury regarding a physician's liability for error of judgment in choosing between approved methods of treatment. The general rule is stated in 48 C. J. 1128, as follows:

Whether errors of judgment will or will not make a physician or surgeon liable in a given case depends not merely upon the fact that he may be ordinarily skilful but on whether he has treated the case skilfully or has exercised in its treatment such reasonable skill and diligence as is ordinarily exercised in his profession. The exemption from liability does not extend to a case where the error occurs by reason of a physician's lack of the knowledge which he should possess or his failure to exercise proper care, thus a physician is liable for the consequences if the error of judgment is so gross as to be inconsistent with the exercise of that degree of skill and care which it is his duty to apply.

Mortality tables, the Supreme Court said, are properly admitted in evidence.

Judgment in favor of the patient was affirmed.—*De Groot v. Winter (Mich.)*, 251 N. W. 425.

<sup>1</sup> *De Groot v. Winter*, 247 N. W. 69, J. A. M. A. 101:1888 (Dec. 9) 1933.

**Workmen's Compensation Acts Tuberculosis Due to Lowered Resistance Following Injury Compensable**—To be compensable under the workmen's compensation act, says the district court of appeal of California, second district, division 1, tuberculosis need not be due directly to trauma. If an injury causes a depleted and weakened condition of a workman and thus renders him more susceptible to tuberculosis germs than he otherwise would have been, or makes him unable to resist the attacks of germs in his system, then disease resulting from such germs is a natural sequence of the condition resulting from the injury. If death occurs, the injury is the proximate cause of death, the disease is but a link in the chain of causation.

In this case a medical expert called by the claimant testified that the workman died from pulmonary tuberculosis and that in his opinion the predisposing cause of the disease was the workman's lowered resistance that resulted from an industrial injury. The employer and his insurance carrier introduced no direct evidence on this point. The evidence showed, however, that the workman might have contracted tuberculosis without first sustaining an injury and that the theory that lowered resistance caused by the injury was the inducing cause of his tuberculosis was "purely speculative." Nevertheless it was error, according to the district court of appeal, for the industrial accident commission to find that although the workman died from tuberculosis the disease was neither caused nor aggravated by the industrial injury and that the claimant was not entitled to compensation—*Baler v Industrial Accident Commission of California (Calif)*, 27 P (2d) 769.

**Issue of Fraudulent Licenses to Practice as "Unprofessional or Dishonorable Conduct"**—Lentine was licensed in 1929 to practice medicine in Missouri. In March 1930 he pleaded guilty in a criminal action in Illinois, which charged that in 1928 he attempted to aid certain unqualified persons to obtain fraudulently licenses to practice medicine in Illinois. In June 1930 the state board of health of Missouri revoked his license to practice in that state, on a charge that he was guilty of unprofessional and dishonorable conduct and was of bad moral character, based on his criminal activities in Illinois just referred to. The circuit court for the city of St. Louis sustained the action of the board, and Lentine appealed to the Supreme Court of Missouri, division number 1.

The Missouri medical practice act (Revised Stats, 1929, sec 9120) provides, in part, as follows:

The board [the state board of health] may refuse to license individuals of bad moral character or persons guilty of unprofessional or dishonorable conduct, and they may revoke licenses or other rights to practice however derived for like causes. Habitual drunkenness, drug habit or excessive use of narcotics or producing criminal abortion or soliciting patronage by agents shall be deemed unprofessional and dishonorable conduct within the meaning of this section.

Lentine argued that his conduct had not constituted unprofessional or dishonorable conduct within the meaning of the statute. The statute, he urged, by enumerating certain acts as unprofessional and dishonorable conduct restricts the meaning of the term to those acts alone and excludes any and all other acts affecting the practice of medicine, however reprehensible, immoral or unlawful they may be.

The Missouri medical practice act, said the Supreme Court, attempts to secure to the people the services of competent practitioners, learned and skilled in the science of medicine, of good moral character and honorable and reputable in professional conduct. The license granted places the seal of the state's approval on the licensee and certifies to the public that he possesses those qualifications. The legislature, in specifying that habitual drunkenness, the drug habit, the excessive use of narcotics, criminal abortion and soliciting patronage by agents shall be deemed unprofessional and dishonorable conduct did not intend thereby to exclude as grounds for the revocation of a license all other acts, conduct and moral behavior of a physician which by common opinion and fair judgment are found to be in their very nature unprofessional and dishonorable. On a showing of any of the things enumerated in the statute, the board of health, and the court on review, is not called on to determine whether such conduct is or is not such as in common judgment is deemed unprofessional and dishonorable, for the statute has expressly declared them so to be. It would not be practicable, however to specify each

and every act or course of conduct which constitutes bad moral character or unprofessional and dishonorable conduct and as to acts other than those named, the statute operates when they are in their nature and by common opinion unprofessional and dishonorable.

The use of the general terms "bad moral character" and "unprofessional and dishonorable conduct" does not render the medical practice act so uncertain, vague or ambiguous as to be unenforceable. Certainty is required, said the court, that in preferring a charge the licensee shall be informed of the specific acts or course of conduct on his part alleged to be unprofessional and dishonorable or the basis of a charge of bad moral character. After due notice of the revocation proceedings, the question whether or not the acts or conduct charged are such as to constitute unprofessional and dishonorable conduct or render the licensee a person of bad moral character, within the purview of the statute, calls for the exercise of judgment and sound discretion on the part of the board of health. The board must hear and weigh the evidence and pronounce a conclusion. If the board orders the license revoked the licensee may then have the finding and order of the board fully reviewed by the courts.

The order of the board revoking Lentine's license was affirmed—*State ex rel Lentine v State Board of Health (Mo)*, 65 S W (2d) 943.

## Current Medical Literature

### AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Case of Pluriglandular Neoplasm.**—Bergstrand reports the following case of pluriglandular neoplastic growth. In the left lobe of the thyroid there was a partly calcified, encapsulated adenoma, the size of a plum. There were numerous tumor metastases in both lungs, the largest as big as a pea and with a reddish gray, rather soft cut surface. There was a large tumor metastasis in the pleura between the sixth and the seventh rib. Examination of the fatty thymus revealed in its lowest part, in front of the pericardium, a tumor as big as a pigeon's egg and of an appearance somewhat different from the foregoing metastases. This tumor was brown and soft presenting a smooth glossy surface. On the lesser curvature of the stomach there was a pedunculated polyp. Microscopic examination of the adenoma of the thyroid showed a strictly circumscribed fibrous partly calcified capsule. There was no infiltrative growth in the parenchyma of the gland. The structure of the tumor varied. In some places the alveoli were small and lacked colloid. In some areas this small folliculated parenchyma was of a still less differentiated shape and the tumor cells forming bands and fields were separated by capillaries. The parathyroid struma in front of the heart had an appearance which the author has found in several other cases of von Recklinghausen's osteitis fibrosa. The tissue consisted of large epithelial cells rich in protoplasm and arranged in solid follicles surrounded by capillaries. They contained practically no fat. Some areas were adenomatous, and in these the cells were large with multiple nuclei of varying size. The protoplasm in these cells was eosinophil. Microscopic examination of the suprarenals revealed a small encapsulated adenoma. The chromaffin cells of the medulla stood out sharply blue in preparations stained with hematoxylin and eosin. In the kidneys vast deposits of calcium were in the parenchymal cells and in the interstitial spaces. The metastases in the lungs

were a parenchymatous thyroid adenoma with the tumor cells arranged in bands or small follicles mostly empty. The tumor of the left humerus was uniform and the structure resembled a struma colloid, with large follicles filled with colloid. Slides from different parts of the skull, the spinal column and the tubular bones showed the osteolytic process characteristic of osteitis fibrosa of von Recklinghausen. The Haversian canals were much widened and filled with connective tissue and giant cells of the osteoclast type, arranged along the walls in small cavities in the bone. There was no evidence of new bone formation, cysts and giant-cell tumors being absent, and the contents of the major marrow cavities of the bones were unchanged.

**Arsenic in Brain and Its Relation to Pericapillary Hemorrhages.**—Osterberg and Kernohan point out that the condition known as acute hemorrhagic encephalitis may be due to the administration of organic compounds containing arsenic. The changed appearance of the brain and spinal cord is due to multiple capillary hemorrhages in the white matter of the central nervous system. Chemical determination shows that arsenic is present in this tissue in relatively large amounts. When organically bound arsenic is administered in the treatment of neurosyphilis, it usually is demonstrable in the central nervous system in varying amounts. Inorganic arsenic, when ingested by accident or with suicidal intent, also accumulates in the central nervous system, but it seldom produces hemorrhages. In the presence of an unexplained gross hemorrhage or of multiple petechial hemorrhages in the white matter of the central nervous system, a chemical investigation for arsenic should be carried out.

**Glomus Tumor**—This tumor is a recent addition to oncology. Adair analyzes ten cases. It occurs frequently beneath the nail and on the hands, arms and legs. In no instance did it occur on the body or the head. Pain is the striking characteristic, produced by the slightest amount of pressure. As a rule the tumor occurred in the later periods of life. The average duration of the tumor was nine years. At first glance the lesion appears to be an intradermal neurofibroma. It is smooth, rounded, elevated and colored from rose to purple. It suggests at times a small hemangioma, but it is a solid tumor. The lesion varies from 4 to 10 mm in diameter. If beneath the nail, it is smaller than when in the skin. In the subungual position the lesions were smaller than when located in other places in which there was no pressure element to change their size and shape. The location, the dark rose color, excruciating tenderness and pain, the size, the solitary nature and the age incidence make diagnosis easy. In only one of the ten cases were there multiple lesions. In eight of the ten cases the lesion was surgically removed and a microscopic study was made. The lesion consists of irregular, tortuous, cavernous blood vessels. The lining endothelial cells are cuboidal and rest on a thin collagenous membrane. Some of the vessels are surrounded by a layer of circular muscle, passing gradually into a zone of "epitheloid" cells. There seems to be no constant or definite relationship between this tumor and the occurrence of any other special type of tumor. The wide variety of lesions accompanying the glomus tumor probably has little or no significance. The lesion is benign. The most satisfactory treatment is surgical extirpation under procaine hydrochloride anesthesia. Eight of the patients obtained immediate relief by this procedure and have remained cured. The best treatment of the lesions in the subungual position is removal of the nail followed by excision of the lesion in the nail bed. Irradiation was employed in one case. To this lesion was applied a square radium plaque of 700 millicurie hours, at 1 cm distance with 3 mm of brass filter. This treatment was later repeated. No visible effect on the lesion resulted from these treatments. The lesion may be radio-resistant. The cases have been traced and examined since treatment for periods varying from three months to eleven years. None have recurred.

**Gas Bacillus Infection**—Orr reviews the literature and describes three additional cases. He found that gas bacillus infection, in what is ordinarily considered clean operative wounds, is rare. Because of the prevalence of gas-producing organisms, the possibility of such infection should be kept in mind. Any sudden postoperative rise in temperature, or unusually severe pain following an operation, should suggest the possibility of beginning gas bacillus gangrene, demanding an immediate examination of the wound. The infecting organism may have its source in infections associated with gangrene and therefore may enter the fresh wound either through the lymphatic circulation or as a direct skin contamination from the gangrenous area. The infecting bacillus of one case undoubtedly was an organism of lower virulence than the average *Bacillus welchii*. At no time was there any alarming

evidence of serious infection in this patient. The mortality rate in the twenty-one collected and reported cases is 71 per cent. This high death rate is probably due to the generally serious condition of this group of patients. It is also possible that there may have been some delay in treatment, since gas gangrene is not usually anticipated when amputations are done through relatively normal tissues. As a therapeutic precaution, it is wise to make anaerobic cultures of all gangrene or ulcerations of the lower extremity when amputation is contemplated. If a positive culture is found, gas bacillus antitoxin should be given before operation.

**Tendon Transplantation in Obstetric Paralysis**—L'Episcopo found that residual deformity in obstetric paralysis is essentially due to contracture of the internal rotators and adductors. Multiplicity of operations devised to correct the resulting deformity proves that no one method is satisfactory. Previous operations have been done only to release contractures. The author presents the following operation, which aims to restore muscle balance at the shoulder between the internal and external rotators. The contracted anterior tissues are released by the Sever technique through the usual medial incision. After the wound is closed a skin incision is made, from 3 or 4 inches long, parallel with the posterior border of the deltoid muscle and long head of the triceps. The incision is carried through the superficial and deep fascia, exposing the deltoid, long head of the triceps and teres major muscles. The long head of the triceps is retracted outward, exposing the tendon of the teres major muscle and the humerus. The tendon is freed at its insertion and detached. The dissection is carried out almost entirely with blunt instruments to avoid injury to important structures. These structures are protected against injury if one keeps close to the teres major tendon throughout the dissection. After the teres tendon has been cut, by inserting a blunt periosteal elevator in front of the tendon and cutting against it, the long head of the triceps is strongly retracted outward, exposing the posterior, lateral aspect of the humerus and the upper part of the origin of the lateral head of the triceps. Then an osteoperiosteal flap is lifted from the shaft of the humerus as close to the short head of the triceps as possible. The tendon of the teres major is buried and sutured under this osteoperiosteal flap and the wound is closed in layers. A plaster-of-paris spica cast is applied with the arm abducted and rotated outward with the forearm flexed and supinated. The new insertion is almost directly opposite the old one and the tendon wraps itself round the humerus from behind laterally instead of from behind medially so that, when the muscle contracts, the humerus must rotate outward instead of inward. The cast is left on for six weeks, then cut open so that it can be used as a splint, and the splint is removed three times a week for massage and gentle passive and active exercises. The splint is discarded three months after the operation, but the exercises and muscle reeducation are continued for at least six months. The author performed this operation on six patients with highly gratifying results.

**Acute Cholecystitis**—From a review of 429 operative cases of cholecystitis, Touroff concludes that 1 Acute inflammatory changes may exist in the gallbladder of a patient presenting minimal or absent clinical manifestations at the time of operation. 2 The pathologic changes range from simple acute inflammation to hemorrhagic, suppurative and gangrenous inflammation, empyema, perforation and pericholecystic abscess. 3 In general, the patients presenting minimal manifestations at the time of operation show a considerably higher percentage of advanced and progressive lesions than the patients showing no manifestations at the time of operation. 4 In a selected series of seventy-five cases, 80 per cent of the lesions were considered to be subsiding or capable of subsidence. The remaining 20 per cent were considered to be progressive in nature. 5 It is impossible to determine the exact nature and extent of the inflammatory lesion before operation in any given case. 6 In cases of acute cholecystitis, if subsidence once begun does not proceed uninterruptedly, fairly promptly and completely, early operation is indicated. 7 In cases of acute cholecystitis in which the clinical manifestations have subsided, early operation is indicated.

**The Carotid Sinus and Sudden Anesthetic Death**—Downs describes the occurrence of sudden respiratory failure in nitrogen monoxide and oxygen anesthesia. He states that no yet known factor is responsible for this failure and that heretofore no treatment has been of any avail. Animal experiments are mentioned, in which this sudden arrest of respiration was duplicated by stimulation of the carotid sinuses in various ways. This experimental respiratory failure seemed in all respects comparable to that occurring clinically. He suggests that this accident may be avoided by scrupulous care not to exert pressure on or just behind the angle of the jaw, that the addition of ether vapor to the gas will render the sinus less responsive to any accidental pressure and that if respiratory failure should occur mechanical artificial respiration with a respirator is the treatment that offers the best promise of success.

**Tannic Acid May Convey Bacteria**—Martin and Fowler found that tannic acid of strengths from 1 to 5 per cent are not effective germicides. The 10 and 20 per cent solutions were found to be germicidal within twenty-four hours. Tannic acid itself may be the agent of conveyance of the bacteria as evidenced by the recovery of a number of bacteria other than

the original. The 1, 2 and 5 per cent solutions produced nine contaminations: gram-positive spore bacillus, four; gram-positive bacillus, three; gram-positive streptobacillus, one; and gram-positive staphylococcus, one. The 10 and 20 per cent solutions showed no growth on the end plates. Owing to this fact, the only explanation of the large number of growths is that the tannic acid itself carried the bacteria into the plates. It was not deemed necessary to find how much less than twenty-four hours would be required to destroy the bacteria, because in the treatment of burns the solutions are allowed to remain in contact with the denuded areas for much longer periods. According to Seeger, the more concentrated solutions of tannic acid, even the lowest used, are highly astringent and tend to cause swelling and edema of the tissues and too rapid fixation of the tannin. This factor alone would prohibit the use of more concentrated solutions in order to derive its beneficial bactericidal property. Therefore the less harmful antiseptic solutions may be of some benefit, since it was found that in the less concentrated solutions of tannic acid with the antiseptics there was an inhibition of bacterial growth.

**Cicatrizing Enteritis**—Donchess and Warren report a case of chronic cicatrizing enteritis involving the entire cecum and ascending colon, without any appreciable change on the proximal side of the ileocecal valve other than a moderate degree of hypertrophy of the muscularis produced through partial obstruction at the valve. They believe that the condition apparently developed after appendicitis. The exact etiology is unknown. The recovery of organisms from the lesions would have been without significance, because of the ease with which the ulcerated mucosa could be traversed. The chief importance of this lesion lies in its mimicry of carcinoma. In all probability, apparent cases of certain intestinal cancers may be explained by the fact that a lesion of this nature was mistaken for carcinoma.

**Hepatic Changes Associated with Obstructed Biliary Passages**—Stewart and Lieber observed that, following surgical decompression of an obstructed biliary system, hepatic pigmentation diminishes progressively in patients who survive the immediate effects of the operation, and the hepatic parenchyma tends to return to a normal condition by the recovery of many of the degenerated but still viable hepatic cells and also by regeneration. There is no evidence that hepatic cells arise from the biliary ducts, which rapidly involute following decompression. Lobular expansion subsequent to regeneration of hepatic cells results in compression and condensation of connective tissue at the periphery. The features of regeneration may be minimal or entirely absent in some livers in which the changes are those of a severe acute hepatitis occasionally complicated by hemorrhage and superimposed infection. Disruption of the intralobular architecture with disorganization and dissociation of hepatic cell cords occurs regularly. The necrosis in the inner third of the lobule often extends into the middle and outer thirds or involves the entire lobule, resulting occasionally in acute diffuse necrosis. Many of the focal midzonal and biliary necroses also enlarge and may form abscesses. In addition, the hepatic cells may be atrophied and distorted and at times show cytoplasmic and nuclear vacuolation. The recently regenerated hepatic cells may undergo degeneration and necrosis. The vascular changes include thrombosis, rupture of the sinusoidal reticular walls, hemorrhage, edema of the perivascular tissue spaces and hyperemia, either focal or general throughout the organ. Physical, chemical and infectious factors probably play an etiologic part in the pathogenesis of these lesions.

**Mussel Poisoning**—During the summer, Stegeman encountered five cases of mussel poisoning in Crescent City. Other cases, some fatal, were reported along the Oregon coast, also for the first time. The first symptoms are generally a feeling of numbness about the mouth and tingling of the hands and feet. Another significant, early complaint is a feeling of "lightness." Generally, recovery is complete and fairly quick. In the fatal cases, death occurs in a relatively few hours from respiratory paralysis. The approved treatment is the rapid elimination of the toxic material by emesis, followed by supportive treatment. Because the toxic material does not generally promote increased peristalsis or diarrhea, purges must be given promptly and in large doses to be effective. However, in view of the rapid absorption of the toxin, the use of cathartics may be questioned owing to the additional shock imposed on the patient. At the first sign of dyspnea, artificial respiration should be resorted to.

\*Acid Base Balance of Gastric Juice Blood and Urine Before and at Intervals After Stimulation of Gastric Juice by Histamine L Martin with assistance of E Steigerwald Mary Lee Carroll and M Morgenstern Baltimore—p 57

**Stimulation of Gastric Juice by Histamine**—Martin observed a number of cases in order to estimate the electrolyte changes in the gastric juice, blood and urine during the period of gastric secretion. Histamine was used as a stimulant, and the gastric juice was continuously extracted during the period of observation. The patients were divided into two groups: those who were able to secrete free hydrochloric acid into the gastric juice and those who were not. The amount of salts lost from the body in the first was about four times that lost in the second group. In the blood of the first group the typical changes were a decrease of chloride and phosphate, and an increase of the carbon dioxide content and serum protein. There was a slight rise of total serum base. This represents a state of relative alkalosis. The urine became more alkaline in the majority of cases. Among the anions, chloride and phosphate fell while the carbon dioxide increased. Of the cations, base hydrogen ion concentration and ammonia nitrogen fell. The author describes instances of atypical changes of both blood and urine and advances hypothetical explanations of these changes. In the achlorhydrias the variations in the majority of the cases were similar in kind but different in

degree from those described. The difference in degree consisted of a smaller loss of electrolyte in the gastric juice and correspondingly smaller variations in the blood and the serum. In the initial specimen, certain distinctive differences between the groups were noted. In the second group the carbon dioxide capacity of the serum fell more frequently and the blood chloride rose more often, although the rises were small. In the urine the change of  $pH$  was apt to be less marked and in a larger proportion of cases the urine became more acid or remained unchanged.

**Relation of Inspiratory Distention to Emphysema**—Prinzmetal observed that experimental bronchoconstriction in dogs first causes pulmonary distention with increased inspiratory position of the chest, and a more negative intrapleural pressure. In four cases of bronchial asthma the intrapleural pressure was found to be more negative than normal instead of more positive, indicating active pulmonary distention by increased inspiratory effort. The prolonged effect of more negative intrapleural pressure causes distention and stretching of the lungs with probable loss of elasticity. This is the first step in the production of structural emphysema. Thereafter the intrapleural pressure rises and the weakened alveolar walls subjected to further strain rupture and coalesce. Direct experiments show that increased carbon dioxide tension and anoxemia also cause a more negative intrapleural pressure and a mean increased thoracic girth. Anoxemia produced by low oxygen tensions has been shown to produce emphysema in rats. The greater negative intrapleural pressure found in bronchoconstriction may be explained by increased resistance to respiration, carbon dioxide retention and anoxemia resulting from bronchoconstriction.

**Operation for Pott's Disease**—Ito and his associates outline incisions and operative procedures for Pott's disease involving the lumbar vertebrae below and including the second (pararectal incision with extraperitoneal approach), for resection of the body of the twelfth dorsal or first lumbar vertebra (oblique incision, similar to that of Bergmann's for nephrectomy) and a preliminary costotransversectomy for resecting the body of a dorsal vertebra. They believe that in performing a radical operation it is not only necessary to be thorough in curettage but also the eburnated bony tissue of the immediate vicinity must be chiseled off as this maneuver definitely favors the subsequent regeneration of bone. A complicating cold abscess heals by mere aspiration of its contents and obliteration of its communication with the original focus. In a

series of experiments on rabbits the authors proved that, when autotransplantation of bone is made into the place of a resected body of vertebra, a new bone is formed on the line of contact between the healthy vertebra and the transplant, the transplant itself grows by proliferation of its own tissue and a weight of 20 Kg is easily withstood by the transplanted segment of the spine. A defect in the body of the vertebra caused by resection may be repaired either by an operation after the method of Albee or by direct transplantation of a piece of the patient's own tibia or rib, without subsequent disturbance of weight-bearing function, as shown by the fact that a kyphosis does not develop and that no increase of a preexisting kyphosis occurs. Of the ten cases in which they employed their technique of radical operation on the vertebrae, all except two cases showed healing by first intention. In one of the two cases, in which a fistula had developed, its spontaneous closure occurred quite early and the patient was discharged in a satisfactory condition a month after operation by the Albee method. In the other case, discharge from the sinus has greatly diminished and there is evidence to indicate its spontaneous healing in the near future.

**Transverse Fractures of Neck of Radius**—Patterson describes a method of operative removal of the head of the radius in children applicable only to complete fractures of the neck, or that portion of the radius between the head and the insertion of the biceps, with displacement, and possibly to epiphyseal separation. The annular or orbicular ligament must be intact. An assistant grasps the arm and fixes the humerus placing one hand against the inner condyle to act as a fulcrum for leverage. Another assistant uses traction on the arm and forces the forearm inward until the carrying angle is obliterated. He also supinates the forearm to relax the supinators. The position is checked by roentgenograms and if the fracture has been reduced, a cast is applied with the arm in complete extension. The cast is worn two weeks and then removed, following which physical therapy is instituted. The elasticity of the ligaments and other joint structures in children enables one to revolve the forearm inward on a vertical axis passing through the inner condyle. The method has been used in two instances with satisfactory reduction.

**Decamethylene Diguandine in Diabetes Mellitus**—Campbell states that the daily administration of 0.025 Gm of decamethylene diguanidine (synthaline) by mouth produced a well defined reduction in the urinary dextrose excretion in a diabetic patient. The maximal effect or complete desugarization of the urine was not reached until the fourth day of administration with 30 units of insulin daily and not until the sixth day without insulin. The failure of the level of urinary dextrose excretion to return in the after period to that of the fore period in the first instance was probably due to a return of the natural tolerance of the patient, brought on by the period of desugarization. This was less evident in the second instance, for the dextrose excretion level in the second after period almost reached that of the fore period. Because of the toxic effect on the liver reported by other investigators, the use of decamethylene diguanidine was discontinued.

**Estimation of Plasma Bilirubin**—Bensley made 100 determinations of the bilirubin content of blood by the van den Bergh and the Thannhauser and Andersen methods in cases with "direct" bilirubin. Both methods were used in each case and determinations were made simultaneously. In subsiding jaundice, the values obtained by the van den Bergh technic are not even approximately correct, loss of bilirubin may be as much as 60 per cent or more. In such cases, therefore, the Thannhauser and Andersen procedure is indispensable. In all other cases, however, including latent jaundice, the van den Bergh technic, although not strictly quantitative, is sufficiently quantitative for clinical purposes.

**Method for Staining Reticulocytes**—The study of Osgood and Wilhelm of methods for reticulocyte staining showed a great number of different technics giving variant results. The following is the most satisfactory technic for staining and counting reticulocytes. Equal parts (5 drops) of oxalated venous or capillary blood and 1 per cent of brilliant cresyl blue in 0.85 per cent sodium chloride solution are mixed in a small test tube. This is allowed to stand at least one minute, it is mixed, and thin smears are made, which are dried in the air as usual. These smears may be counted at any time within twenty-four hours, but if a permanent preparation is desired they should be counterstained with Wright's stain by the usual technic. The brilliant cresyl blue solution keeps well but should be filtered if debris appears on the slide. An area is selected on the slide which contains from 50 to 75 red cells per oil immersion field. All the cells are counted and all the reticulocytes in as many adjacent fields as is necessary to give a total of 500 red cells if the count is more than 5 per cent, or 1,000 red cells if the count is less than 5 per cent. With this method a count of 23.6 per cent was obtained in the blood which gave 17.6 per cent with the best method previously studied.

**Paragonimus Westermani**—Bercovitz and Rogers report a case of abdominal involvement in a patient with lung fluke (*Paragonimus westermani*). The ova, unevenly distributed, were found in the lymphoid tissue and lymph sinuses but not in any of the blood vessels of nodules removed from the mesentery and parietal peritoneum. Surrounding each group of ova there was evidence of cloudy swelling and hyperplasia of the endothelial cells. Degeneration of the nuclei took place in the nodules surrounded by the clustering ova. No adult worms were found in any of the tissues. The clinical impression was that of a generalized malignant condition of the abdomen.

 \*New Method for Radiographic Exploration of Mediastinum and Concealed Portions of Pulmonary Fields P M Andrus London Canada—p 97

**Roentgenographic Exploration of Mediastinum**—Andrus outlines a method for exploring the mediastinum and concealed portions of the pulmonary fields, by the employment of which glandular masses are frequently visible which are not seen in tube-centered or the conventional oblique exposures. Their position in relation to the trachea or main stem bronchi is also apparent. Such visualization depends on the presence of calcium, because of the density of the vascular structures with which they are contrasted. Complete calcification is not necessary, as scattered lime may indicate the presence of caseo-calcareous deposits. It would seem that an improved visualization of the occurrence, extent and relationships of the glands in the region of the tracheal bifurcation can be expected to constitute an important advance, especially in the study of tuberculous infection in children. The author suggests off-centered thoracic exposures for the roentgenography of the concealed portions of the pulmonary fields and the region of the tracheal bifurcation, in anticipation of a more widespread experience than is possible in a single center, determining whether the procedure has anything of importance to add to medical methods.

Pulmonary Tuberculosis After Sunbaths A Hope Gosse and G S Erwin —p 15

**Pulmonary Tuberculosis Following Sunbaths**—Gosse and Erwin made a study of the relation, if any, between sunbathing and pulmonary tuberculosis. Careful inquiry in each case elicited the fact that, out of sixty-six cases of pulmonary tuberculosis admitted to the hospital between August and December 1933, the onset or exacerbation of symptoms in eleven cases followed sunbathing. The age incidence ranged between 19 and 33, years common to sunbathing and to the production of the exudative type of the disease, which was the one present in the eleven cases on roentgen appearances. Although there was a considerable proportion of the fibroid type of disease among the other fifty-five patients, each one of them denied indulging in sunbathing during the summer, and an absence of sun pigmentation supported their statements as far as it could. The fibroid type was present in some patients whose age was greater than the average of sunbathers, and in others who had passed the exudative stage. Many of these patients had a long history of tuberculosis and had been deliberately warned by their doctors against the danger of sunbathing. That the abnormal exposure of the usually covered skin surfaces to the action of the sun's rays aggravates the development of pulmonary tuberculosis is a conclusion suggested by these eleven cases. The authors believe that this new social custom has elements of danger if indulged in extensively and indiscriminately. The exact manner in which sunbathing may aggravate tuberculosis is not understood, that is, whether long sunbaths raise the body temperature in healthy young adults or possibly only in those in a hyperallergic state. For the latter possibility there is some support in the fact that several patients showed an immediate reaction in the form of malaise and sweats, as well as a delayed reaction from some weeks to three or four months later in the more dramatic form of hemoptysis among other symptoms.

**Lympho-Epithelioma of Nasopharynx and Tonsils**—Cappell studied twelve cases of malignant disease of the nasopharynx, tonsils and pharynx and believes that they are of epithelial origin, arising from the specialized epithelium of the pharyngeal lymphoid tissues. He emphasizes the value of silver impregnation of the reticulum as a means of demonstrating the structure of such growths. These tumors show distinctive clinical and pathologic features and may justifiably be separated from other neoplasms under the name of "lympho epithelioma." Two main types of histologic structures have been recognized, one corresponding to the classic lympho-epithelioma of Regaud and the other to the lympho epithelioma of Schmincke. It is shown that these are not different types of neoplasm but represent merely quantitative differences in the mode of growth and spread of the tumor cells. Evidence for regarding transitional cell carcinoma of the nasopharynx and the tonsil as a different form of neoplasm from lympho epithelioma is not definitely established in the present observations and it is believed that the two are at least closely related. Lympho-epitheliomas are highly radiosensitive and the value of radiation therapy in contrast to surgical excision is clearly demonstrated in the present series of cases.

**Sarcoma of the Spleen**—The spleens removed by McNee from two patients represented two types of the same variety of primary lymphosarcoma of the spleen, arising from the lymphoid malpighian bodies, as indicated with certainty by the recognition of a central arteriole in many nodules of the growth. In the first patient there were no obvious metastases at the time of the operation, but now, four years later, a mass of uncertain nature is present in the left side of the abdomen. In the second patient the lymph nodes of the groins were enlarged and invaded by growth of the same histologic structure for more than a year before splenectomy was performed. No further secondary growths were observed during the operation and no necropsy was held. Two spleens apparently identical with the author's first case have been recorded, one by Forx and Roemmele and one by Ross. This is the type which Paraf and Abaza, speaking of the case reported by Forx and Roemmele describe as "splenome nodulaire" in contrast to the far more numerous examples of "splenome massif" in which the spleen contains a single large mass, or several masses, of

lymphosarcomatous growth. The term "splenome" is obviously used in an entirely general sense. The second spleen described here would appear to occupy an intermediate place, but approaching more the first than the second category of Paraf and Abaza. Ross regards the essential pathologic change as a progressive hyperplasia of the follicular reticulum cells—a lymphoid reticulosis rather than a true tumor growth. In view of the abundant mitotic figures exhibited in the cells of both cases, and of the certainty of growth of the same kind at a distance in one case and the possibility of secondary growth in the other, the author prefers to regard the whole process as a true tumor rather than as any form of hyperplasia. Since it is evident that in these cases metastatic spread is uncommon, the correct treatment would seem to be removal of the spleen provided a correct diagnosis can be made.

**Demonstration of Bacterial Capsules**—According to Howie and Kirkpatrick, a simple and reliable method for the demonstration of bacterial capsules consists in adding to a loopful of exudate or of culture suspended in broth on a microscope slide a drop of dilute phenolphthalein, followed by a drop of a 5 to 10 per cent solution of eosin and then making films. The bacterial bodies are positively stained and the capsules are seen by "relief staining." Suspending capsulated organisms in water hinders or completely prevents the demonstration of the capsules but does not destroy the latter. Capsules and bacterial bodies can still be demonstrated in cultures of pneumococci cleared by the addition of bile salt.

**Cultivation of the Gonococcus**—McLeod and his collaborators maintain that cultural demonstration of the gonococcus is superior to demonstration by the examination of smears in chronic cases of gonorrhea in both sexes, and in all cases in the female, especially when material for examination is taken from the cervix. There is, however, a residue of cases positive in smear and negative in culture which with the methods at present available is larger than can be explained by false positives. A small proportion of false positives is undoubtedly recorded if diagnosis is determined by microscopic examination of gram-stained smear preparations only. Culture of many strains of gonococcus is promoted by incubation in air containing 8 per cent carbon dioxide. The recognition of gonococcus colonies in culture is greatly facilitated by the use of the direct oxydase reaction, and the employment of this reaction results in a marked economy of time.

Effects of a Prolonged Drought on Disease Carriers F. G. Cawston—p. 195  
Pellagra in Sudan N. L. Corkill—p. 196

**Melanoprecipitation Reaction in Malaria**—Greig and his associates investigated Henry's melanoflocculation reaction in malaria. Melanin pigment extracted from human hair by hydrolysis with hydrochloric acid and dialysis through a celloidion membrane has been found to give more satisfactory results than the use of crude aqueous suspensions of ox choroid membrane. By their technic it is possible to obtain a quantitative estimation of the reaction property of malarial serum with melanin pigment. The appearance, the rise and the fall of this property during the course of an illness have been accurately traced by the induction of benign tertian malarial infection in selected persons. The nonantigenic properties of melanin pigment and the low thermolability point (55 C for half an hour) of the reacting power in positive malarial serum have been demonstrated. As evidence of the fact that the reaction is due to the presence of melanin pigment and not to any other, an analogous reaction has been shown to occur between dioxyphenylalanine, the precursor of melanin and

malarial serums. The authors suggest the term melanoprecipitation reaction as a suitable name for the phenomenon. Their procedure consists of a row of ten Wassermann tubes laid out on a rack with a corresponding row of narrow agglutinating tubes opposite them. To each of the Wassermann tubes 0.4 cc of distilled water is added, and in the first tube 0.4 cc of the patient's serum is placed. From the first tube 0.4 cc of 1:2 dilution of serum present there is withdrawn and added to the second tube, from which in turn is withdrawn the same amount, and the process repeated until the ninth tube is reached, from which 0.4 cc is removed and discarded. With a pipet, 0.4 cc of melanin is added to all the ten tubes. The 1 cc measuring pipet is discarded and a Pasteur quill tube is substituted, with which mixtures are transferred from the Wassermann tubes to the narrow agglutinating tubes, commencing with the tenth one and working backward. The ultimate dilutions of patients' serum are thus 1:4, 1:8, 1:16, 1:32, 1:64, 1:128, 1:256, 1:512 and 1:1,024, respectively, the control tube (the tenth) containing melanin solution plus distilled water. The entire series should on examination be clear and transparent in appearance with no trace of particles in suspension, it is now incubated at 37 C for five hours and the results are read at the end of that time.

\*Pellagra in Sudanese Millet Eaters N. L. Corkill—p. 1387  
Practical Treatment of Rickets in Children J. R. W. Hay—p. 1390

**Pellagra in Millet Eaters**—Corkill observed a pellagrous condition in 103 members of a tribe in Sudan, due no doubt to millet. Certain physical signs were "sulphur-flake" sebaceous dysfunction on the forehead, wings of the nose, cheeks and chin; a stomatitis characterized by the pronounced impression, as if in wax, of the lateral aspects of the closed rows of teeth on the mucous membranes of the cheeks; glossitis of various forms; blueness or blackness of the gums in patches or to complete involvement and in certain subjects a deepening of the natural pigmentation on the forehead and cheeks. The most common subjective symptom was a burning pain in the hands, feet, head and interscapular region. This pain came at night or on going into the shade after being in the sun. It came daily in the hot dry season. In the rainy season it disappeared. Some subjects got it at seasons other than the hot dry season if they worked hard. The pain was often associated with swelling of the skin followed by desquamation. Other common symptoms were a gnawing or "hot" pain in the epigastrium, weakness, wasting, flatulence, vomiting, diarrhea, pains in the joints, lumbago, formication, vertigo, sleep dysfunction and mental disorder. The author suggests a new theory of the causation and nature of pellagra in that 1. The fundamental condition is a lack of cholesterol and vitamin A and D in the food, lack of vitamin C being a contributory factor. 2. Pellagra is largely allergic, and the evils resulting from cholesterol and vitamin deficiency contribute to the syndrome, as do also cereal toxin effects. 3. Pigmentation is protective against the actinic and tactile traumas affecting the skin of pellagrins. 4. Vitamin D, and not the hypothetical water soluble vitamin B, is the antidermatitis vitamin.

**Roentgen Therapy of Malignant Diseases**—Coutard points out that the two principal factors in roentgen therapy are the energy and the time. They must be considered in their relation to the cancer cells and to the vasculoconnective tissue and the general tissues of the site from which the cancer is developing. In the course of treatment the principal guides should be the roentgen reactions of the vasculoconnective tissue of the covering epithelium and of the cancer cells. When one

is irradiating a small cancer, embryonic in type, the treatment can be completed in a short time, about twenty days, the epithelial roentgen reactions may be relatively intense, on condition always that their duration never exceeds fifteen days. When one is irradiating a cancer less embryonic in type, the treatment should be of longer duration, and the epithelial roentgen reactions should be slight. When an extensive cancer is being irradiated through fields of large dimension, as in the case of cancer of the uterus, the treatments should be forty days as a minimum, the cutaneous roentgen epidermitis should not be exudative and the roentgen epithelitis of the vaginal, intestinal or vesical mucosa ought to be slight. Symptoms, even temporary, of cystitis, proctitis or enteritis should be avoided. The question of energy—cancericidal dose—is essential in the treatment of an undifferentiated embryonic, roentgen sensitive cancer, and it is more important than the question of time. The energy seems to be directly destructive, the chronology is, above all, protective, since it allows the preservation of the supporting tissues in order to avoid accidents. The question of time is more important than the question of energy in the treatment of a differentiated roentgen resistant cancer. The energy should not provoke a destructive effect. Owing to a slow chronology and to weak daily doses, the disappearance of the cancer cells seems to follow a cellular evolution resembling the normal evolution. In determining the longer duration of treatment, one should aim at the perfect preservation of the supporting tissues so that the evolution effect may become possible.

**Treatment of Cancer of the Lip by X-Rays**—When not more than half the depth of the lip from the edge to the reflexion of the mucous membrane to the alveolus is involved, Molesworth employs the following procedure. The lip is everted and fixed with strapping. After this a dose of 700 roentgens of the quality 120 kilovolts constant potential, with 1 mm of aluminum filter, is delivered to the inner surface of the lip over a semicircle, 1 cc of apparently normal mucous membrane being allowed to come into the beam. Of this approximately 500 roentgens survives at the opposite (skin) surface of the lip. Then the lip is allowed to fall back into normal position and a similar dose is delivered to the skin surface over a similar area, a piece of lead rubber being placed between the lip and the teeth and alveolus. This brings the dose at each surface to 1,200 roentgens and the distribution throughout the lip is quite even. A dusky red reaction with some exudation occurs on the surface of the skin and there is frank erosion on the mucous surface. This begins about eight days after irradiation and lasts for three weeks. Thereafter the improvement is rapid and at the end of ten weeks the lip is well with no remaining infiltration. In the author's fifty cases in which he used the foregoing technique the tumor has disappeared. There were two recurrences—marginal in each case and due to failure to expose a sufficiently wide margin of apparently healthy tissue. In only one case have the regional glands subsequently shown carcinomatous deposits. These two patients were operated on subsequently at an early stage with apparent success.

Simple Method of Estimation of Proteins of Blood Serum and Its Value in Tuberculosis W Pagel and L B Stott —p 454

**Estimation of Proteins of Blood Serum Its Value in Tuberculosis**—Pagel and Stott examined more than 100 cases of all forms and degrees of pulmonary tuberculosis by the following method which they found to be reliable for clinical purposes. Into six tubes is placed 0.5 cc of physiologic solution of sodium chloride. To tube 1 is added 0.5 cc of fresh filtered ox bile, from which 0.5 cc of the mixture is transferred to tube 2. This process is continued up to tube 5, and 0.5 cc of the mixture from tube 5 is discarded. The last tube (6) being a control tube contains only 0.5 cc of physiologic solution of sodium chloride. After this, 0.5 cc of 1:7 dilution of the serum to be examined is added to each tube and all tubes are heated until coagulation of the proteins appears in the last tube. The results are recorded immediately, and after twelve hours standing at room temperature. There are all degrees of coagulation, from intensive opacity like milk (++++), less opacity (+++), faint transparency (++), gradually falling (+±), to entire clearness (—). The authors believe that the bile test as a measure of the amount and behavior of the proteins of the blood serum gives a good indication of the extent and the activity of the anatomic changes in the majority of cases of pulmonary tuberculosis. Cases of hematogenous tuberculosis of the lung especially showed a strong bile test. Exudative infiltrations with a tendency to liquefaction and the development of more than one cavity reinforce the reaction, while local fibrosis of the foci and cirrhotic changes decrease the reaction. Marked anatomic change, such as cavitation and cirrhotic tuberculosis, can show a favorable bile test if the general condition is good. The number of such cases is small. In cases of albuminuria or loss of albumin from the body by any other way (sinuses), the bile test fails. In such cases the blood cell sedimentation gives reliable results. In many cases the bile test is in advance of the blood cell sedimentation test and coagulation band determination.

**Influence on Respiratory Exchange of Pharmacologic Agents**—The object of the investigations of Labbe and Rubinstein is to determine whether substances that stimulate the parasympathetic system and the pneumogastric exert a simultaneous action on the respiratory exchanges, and whether substances like epinephrine, with specific sympathetic action, possess an effect on respiratory exchange opposite to that of substances which, like physostigmine, paralyze the sympathetic. The subjects for these tests were examined in the morning after a twelve hour fast and a half hour rest lying down. The basal metabolism was measured by the usual technic. The respiratory exchanges were then remeasured at the end of ten minutes, thirty minutes and each thirty minutes thereafter for three hours. This gave information as to the time at which the greatest modification of metabolism occurred. The results are expressed in percentages of exchanges in relation to the normal basal metabolism of the subject. The respiratory quotient and the respiratory debit per minute were measured, the rapidity of the pulse and the arterial pressure were taken and the surface was calculated from the Du Bois tables. The substances examined, acting in different ways on the vegetative nervous system, exert a different qualitative and quantitative action on respiratory exchanges. Epinephrine increases the exchanges, while insulin and acetylcholine lower them. Atropine, which paralyzes the vagus, produces a double phased reaction the first is lowering of the respiratory exchange rate, which is related perhaps to the initial stimulation of the vagus, the second is elevation of the respiratory exchanges, which is the paralysis of the vagus. There is consequently an antagonism between the excitants of the sympathetic and the vagus as far as respiratory exchanges are concerned. Different persons react unequally to these substances. Those who react strongly to epinephrine react feebly to atropine and acetylcholine. Conversely those who react weakly to epinephrine react strongly to atropine and acetylcholine. Subjects reacting by strong hypermetabolism to epinephrine exhibit other signs of sympathetic stimulation such as rise in blood pressure and increased pulse rate. Those who have a weak metabolic reaction to epinephrine and a strong reaction to atropine and acetylcholine show symptoms of vagal stimulation such as lowering of the arterial tension and slowing of the pulse rate. These correlations lead to the opinion that tests of the basal metabolism after injection of substances stimulating the sympathetic or the vagus are capable of throwing light on the condition of the neurovegetative system.

 Recovery L Jame A. Jude and E Aujalet—p 490

**Gonococcus Complement Fixation Reaction**—Jame and his collaborators conclude that the gonococcus complement fixation reaction as practiced according to the technic of Gauran (1923) is specific. In acute blennorrhagia it is however of little diagnostic interest, since microscopic examination of the urethral discharge is simple, rapid and to the point. It is of some value in the differential diagnosis of nongonorrheal urethritis. In chronic blennorrhagia its diagnostic value is relative. A positive reaction is confirmatory evidence of the

gonococcic etiology of the discharge, but no conclusions can be drawn from a negative reaction. In doubtful cases numerous reactions must be performed in series. In genital and extragenital complications the reaction manifests its greatest possibility and specificity. In arthritis, especially, it is rarely wrong. As a sign of cure a negative reaction in a patient clinically well allows confirmation of the recovery. The passage from a positive to a negative reaction after the clinical cure suggests the recovery parallels the clinical cure. A reaction remaining positive two months after the clinical cure suggests the persistence of a gonococcic focus. Vaccinotherapy modifies these conclusions. The positivity of the serologic reaction may be longer, and it is only at the end of about four months a new reaction can give useful evidence on the evolution of the disease.

 L Baldenweck—p 942

**Voice Imitation in Diagnosis of Simulated Deafness**—Baldenweck describes a simple sign which he considers useful in the diagnosis of simulated deafness. It is based on the phenomenon that when two persons converse they instinctively use a similar vocal pitch. Thus, when one addresses another in a high voice, the other responds in the same fashion. Summar moderate degrees of true deafness observed in persons with a sound apparatus, the hearing limits of the low conversational voice and strong conversational voice are determined. At the greater distance the voice is then varied from loud to low. The subject may not respond at all and has not heard or is a well schooled malingerer. If this is so, tests by other methods must be used. He may respond but without following the changes of voice intensity. In this case he is simulating deafness. This would indicate marked exaggeration of the must try other means. If positive, it is a valuable proof of simulation.

 Traumatic Tetanus and Care for Surgical Wounds H von Seemen  
 —p 667  
 \*Etiology of Relapsing Cystitis H Wildbolz—p 670

**Operation for Cryptorchidism**—Matti says it is erroneous to assume that a truly retained testicle may still descend spontaneously during the first years of life or up to the period of puberty. Subsequent descent is possible only in the case of so-called floating testicles drawn to the internal inguinal ring by the cremaster but which can be brought down into the fundus of the scrotum without exerting a strain on the funiculus. Since in all forms of retained testicles the relative shortening of the spermatic cord increases with the years, the prospects of a tensionless transplantation of the testicle to the normal place becomes constantly lessened. For this reason the author recommends early operative correction of cryptorchidism at the end of the first year of life or in the course of the second year. He asserts that in such early operations the orchopexy,

which frequently has injurious results, can as a rule be dispensed with. A testicle that can be placed into the scrotum without great tension may be held in position by a suture that narrows the subcutaneous isthmus. The author is convinced that an improvement in the results of the treatment of cryptorchidism can be obtained only if early operative treatment is adopted as a general rule.

**Etiology of Relapsing Cystitides**—Wildbolz observed that the stasis of secretion in the female urethra predisposes to cystitis. He also noticed that women who consulted him on account of relapses of cystitis quite frequently had the external urethral orifice deep in the vagina (indication of hypospadias) and also an unusually high posterior vaginal commissure, which inhibits the proper discharge of the vaginal secretion. In some of these women the abnormally high vaginal commissure was the result of plastic repair of the perineum, and in others it was congenital. There was always a stasis of vaginal secretion behind the transverse fold of the vaginal introitus. The urethral orifice was constantly surrounded by the secretion. The lips of the orifice were reddish and swollen, and the urethra contained purulent secretion. The cystoscopic examination of these patients did not disclose a cause for the relapsing cystitis in the bladder or in the upper urinary tract, and it was therefore logical to assume that the stasis of the secretion by the high vaginal commissure with backflow into the urethra was the cause of the frequent attacks of cystitis. This assumption was corroborated by the fact that the relapses of cystitis ceased as soon as the discharge of the vaginal secretion was facilitated by a median incision into the posterior vaginal commissure. The author emphasizes that the possibility of this undesirable result of a high posterior vaginal commissure should be kept in mind in case of plastic repair of the perineum.

- Clinical and Surgical Considerations of Hydatidiform Choleperitoneum and of Hydatid Peritoneum O F Mazzini—p 742

**Pyelovenous Reflux and Intrarenal Absorption**—Ciocca conducted experiments on dogs and rabbits. He found that micro organisms in suspension, introduced into the renal pelvis through the ureter in ten minutes time and usually at a pressure of scarcely 10 mm of mercury, may be recovered from the blood stream of the efferent vein. With opaque substances the author obtained roentgenologic images attributable to pyelocanalicular reflux not only in the kidney of the dog but also in that of the rabbit. The average degree of pressure to make this phenomenon visible on the plate usually begins at 40 degrees for the rabbit and at 60 for the dogs. At high pressure of from 80 to 100 degrees for the rabbit and from 120 to 140 for the dog, a direct pyelovenous reflux is shown in the live animals with yielding of the pressing piston, and also in the extirpated kidney under roentgenographic control and by direct observation of the reflux of the liquid injected into the renal vein. As an explanation of his results the author cites the factor of intrarenal absorption (previous pyelocanalicular reflux) through the epithelium of the tubules. This is also the reason for certain renal infections such as cortical abscesses and infectious nephritides, without calling into play the pyelovenous reflux, which is a traumatic, accidental and violent phenomenon.

**Action of Blood on Bacteria in Peritoneal Cavity**—Teneff experimented with rabbits to study the influence of the blood on the development of micro organisms in the peritoneal cavity. He injected bacteria into the peritoneal cavity after having induced a hemoperitoneum by cutting the mesenteric artery. In the control rabbits he gave only an injection of bacteria in equal quantity. He used virulent cultures of *Staphylococcus pyogenes-aureus*, *Staphylococcus pyogenes albus*, *Bacillus coli* and *Bacillus prodigiosus* and followed their numerical behavior several days after the injection. The author's results demonstrate that normally the peritoneum has a notable

resistance to pathogenic germs which, when a certain quantity of autogenous blood is present, increases in the beginning, and the micro-organisms are destroyed in a large proportion by the physiologic bactericidal power of the blood. In the second stage (after from six to eight days) a rapid numerical increase in micro-organisms of the peritoneal cavity is observed which culminates sometimes in the appearance of a peritonitis, probably because the blood, being altered and exhausted in its bactericidal power, serves as food for the development of the micro-organisms.

**Medium for Isolation of Gonococci**—Castillo and Herraiz report satisfactory results in the isolation of gonococci "in vitro" by the use of a new medium. In its preparation 500 Gm of beef, deprived of aponeurosis and fat, and 20 Gm of caked brewers' yeast in 1,000 Gm of water are left in maceration for fifteen hours. These ingredients are then boiled for fifteen minutes and filtered, enough water being added to make the original volume. Then 20 Gm of Witte's peptone and 0.5 Gm of potassium chlorate are added. The  $pH$  is then fixed at 7.6 and the preparation boiled again but only for a short time to precipitate the phosphates, and then filtered again. Agar-agar is then added in a proportion of 3.5 per cent, that is, 3.5 parts of agar-agar to 96.5 parts of the preparation. The preparation is then sterilized for three successive days for thirty minutes at a time in high pressure steam. After it is melted at a temperature of 45 C, rabbits' or horse's blood is added in the proportion of 20 per cent, that is, 20 parts of blood to 80 parts of the preparation. The medium is then ready to be placed in separate sterile receptacles for use.

**Nuclear Deviation in Infantile Tuberculosis**—Blanco Otero studied the modifications of the index of nuclear deviation forty-eight hours after the intradermal injection of a 1:10,000 solution of Koch's old tuberculin in a group of fifty-two children who suffered from different forms of either active or inactive (latent and residual) tuberculosis and five non-tuberculous children. The author, considering the index of nuclear deviation as represented by a fractional number, regarded the variations of the index, not exceeding one fifth (either in increase or in diminution) to the original fractional number, within the type of invariable reaction. The most frequent reaction in the whole group was that of the invariable type (60 per cent). The author interprets the invariability of the index as caused by a reaction of the organism to the stimulus of tuberculin with a parallel and proportional production or diminution of both immature and mature cells (myelocytes, juvenile cells and staff cells and segmented forms, respectively). The increase of the index is interpreted by an overproduction of immature cells, and its diminution by an overconsumption of mature cells by the organism during the reaction. There is no relation between the reaction of the augmentative type and the grave forms of tuberculosis in children. Only in cases of secondary infiltration were the variations of the augmentative type higher than those of the diminutive and invariable types (66.68 per cent). The variations of the augmentative type were also high in the group of nontuberculous children (40 per cent). This group, however, had the same figures for the augmentative type as for the invariable type of reaction. The author concludes by saying that up to the present time no prognostic or diagnostic value

can be given to the variations of the index of nuclear deviation following the intradermal injection of tuberculin in infantile tuberculosis

### Minerva Medica, Turin

Ketogenic Diet in Bronchial Asthma L Montagnini—p 877  
Protein Diet in Diabetes Mellitus S De Candia—p 884

### Ketogenic Diet in Bronchial Asthma—Montagnini states

that in every asthmatic attack factors arise which influence the acid base equilibrium. If the asthmatic attack is partial, only a part of the bronchial tree is involved in the spasm with a corresponding number of alveoli. Thus through the increased respiration in deep respiratory movements an amount of carbon dioxide greater than normal is eliminated resulting in a condition of gaseous alkalosis of the blood. If the spasm involves the greater part of the bronchial tree there is an acute retention of carbon dioxide in the poorly aerated alveoli with consequent gaseous acidosis. That the elimination of carbon dioxide may be profoundly and rapidly changed during an asthmatic attack is demonstrated by the basal metabolic rate. The author placed twelve asthmatic patients on a ketogenic diet consisting mainly of broth, meat, egg egg white and some green vegetable (spinach). Some patients were in grave asthmatic conditions lasting several days at a time while others had frequent and violent attacks. In these patients no other forms of hyper-sensitivity were manifest, such as habitual urticaria or the edema of Quincke. Urine was collected every twenty-four hours after which the daily quantitative determination of the acetone and the beta-oxybutyric acid was made. The alkali reserve and the leukocytic formula were determined before and after the diet. During this period the patients were not subjected to any other treatment. The patients showed no ill effects from the diet and the results were encouraging. The author does not believe that there is a primary tendency to alkalosis in bronchial asthma due to the constitution of the asthmatic patient which brings on the attack. He maintains, however, that the acidifying method depresses the vagal tonus and stimulates the sympathetic and as such is a favorable element in the treatment of bronchial asthma. Although he observed a disappearance of crises and general improvement in all cases, he maintains that the acidifying diet is essentially a palliative treatment the effects of which are felt only during the period of treatment since the state of artificiality produced equilibrium lacks stability and must be continually stimulated. The author maintains that the degree of eosinophilia during the diet is completely independent of the variation of the alkaline reserve because the elevated acidotic condition does not bring on the disappearance of the eosinophils and the alkalotic condition does not tend to increase them.

### Cephalalgia Following Spinal Anesthesia—Zappala

studied 100 patients presenting cephalalgia following tutocain and epinephrine spinal anesthesia. He found in the majority of cases that cephalalgia is accompanied by marked hypotension of the cerebrospinal fluid. The author experimented with intravenous and subcutaneous injections of various drugs such as caffeine, ephedrine an epinephrine-ephedrine preparation and ergotamine tartrate to combat the hypotension that is sometimes thought to be the cause of headache. He found that all have only an evanescent effect. The author advocates intradural injection of a 1 per cent solution of dextrose in severe and obstinate cases until the headache disappears. In fact it gener-

ally disappears during injection and when the manometer shows a pressure of from 21 to 23. According to the author, the volume action of the solution injected in the hypotension disappear at once and therefore also cephalalgia, while the slightly irritating action of the dextrose on the choroid plexus removes its temporary inhibition of secretion of the fluid. The author concludes that the reflex inhibition of the choroid plexus is the true cause of hypotension.

### Venous Pressure in Mitral Stenosis—Espejo Sola

considers the rise in venous pressure of great importance in early diagnosis of cardiac decompensation in cardiac and vascular diseases. He compares the figures of arterial pressure (maximal, minimal and mean) with those of the venous pressure in patients with mitral stenosis hypertension and other cardiac diseases. He concludes by saying that in compensated mitral stenosis with and without complete arrhythmia both the arterial and the venous pressure were normal. In decompensated mitral stenosis with and without complete arrhythmia the arterial pressure was either normal or approximately normal while the venous pressure was high. In auricular fibrillation the venous pressure does not undergo the systolic modifications to which the arterial pressure is constantly subjected, owing to the differences in the amplitude of the cardiac pulsations. The oscillometric index was held between 3 and 5 in compensated and decompensated mitral stenosis whether or not complicated by complete arrhythmia. In arterial hypertension complicated with decompensated complete arrhythmia, the venous pressure was high. In other decompensated cardiopathies with complete arrhythmia the arterial pressure was normal, while the venous pressure was high.

### Lead Encephalopathy—Following a review of the literature

in the course of which he points out that the opinion still differ about the nature of lead encephalopathy, Schwaib gives the histories of two cases. The two cases resemble each other in that the patients had attacks of convulsions and signs of lead poisoning. The first patient presented the aspects of lead poisoning with the lead line on the gums and with the typical changes in the blood picture. The neurasthenic condition that existed in the beginning was doubtless the precursor or atypical onset of the later severe nervous disorders. Gradually there developed inflammatory processes of the auditory and optic nerves. After an observation of two months the symptomatology of lead encephalopathy developed rather suddenly with epileptic convulsions pyramidal symptoms and psychic disturbances. The condition improved slowly but there were several relapses with impairment of the consciousness. The second case described by the author demonstrates how

difficult may be the differentiation of lead cnecephalopathy from other conditions. The case was finally cleared up by the post-mortem examination, which revealed no signs of lead poisoning but rather a severe cirrhosis of the liver with contraction of the liver and splenic tumor. The author points out that the terminal stage of the cirrhosis could readily be mistaken for lead cnecephalopathy, although diarrheas do not belong to the aspects of lead poisoning and the splenic tumor should have pointed to a different diagnosis. The cirrhosis of the liver led to hepatic coma with manifestations of stupor, anxiety and convulsions, which, in view of a former lead poisoning, were at first interpreted as the symptoms of lead cnecephalopathy. However, the final expert testimony was to the effect that the patient had died of cirrhosis of the liver.

**Local Application of Vitamin A in Treatment of Wounds.**—Horn and Sandor employed an ointment, containing in each cubic centimeter 2,000 units of vitamin A, in the treatment of new injuries. They observed that the healing process is influenced favorably. The secondary infection is inhibited by the acceleration of the formation of granulations. In the treatment of suppurating wounds, the ointment furnishes a protective layer between bandage and wound surface. The discharge of the secretion of the wound is facilitated. The formation of granulations is greatly increased, the disintegration of necrotic portions is promoted and the entire healing process is considerably accelerated.

Pathogenesis of Renal Dwarfism A. Loeschke—p. 11  
Congenital Duodenal Stenosis During Childhood W. Ziegler—p. 36  
Fetal Chondrodystrophia Case B. Szendi—p. 49

**Pathogenesis of Renal Dwarfism.**—In the first part of his study Loeschke discusses the growth disturbance in renal dwarfism. He points out that, although the chronic renal disturbance and its sequels has no doubt a certain significance for the growth of the organism, there are nevertheless many factors that speak against its primary importance. He thinks rather that a congenital component, that is, a defective general constitution, is the most important factor. This assumption is borne out by manifestations of degeneration in the ancestry, familial occurrence of renal disturbances in general and of renal dwarfism in particular, occurrence of growth disturbances before the onset of the renal symptoms and independent of the state of the disturbance, and occurrence of other malformations on or outside of the urogenital tract. All these factors may be found alone, several together, or entirely absent. The author differentiates two types of renal dwarfism. As representative of one type he cites the case of a renal dwarf with intact renal function. This case proves that renal dwarfism may occur without impairment of the renal function and thus speaks against a modification of the growth process by the renal disturbance. The growth of renal dwarfs is frequently unproportional and in figure and general development they may be infantile. The author thinks that in congenital hydro-nephrosis growth disturbances are more frequent than is commonly assumed. In the discussion of another type of renal dwarfism it is shown that it is not dependent on the existence of a chronic interstitial nephritis. In the second part of his paper the author discusses the metabolism in renal dwarfism and the pathogenesis of renal rickets. Here he shows that the phosphatemic curve is higher in renal dwarfism than in children with normal elimination. This corroborates Mitchell's thesis of the stasis of phosphates. The blood sugar curve of renal dwarfism is somewhat higher and the epinephrine reaction is more pronounced than is the case in normal children. This is most likely the result of the acidotic metabolic condition of the children with chronic renal disease. The diastase elimination of children with renal dwarfism is not increased but is within normal limits. The author advances evidence for his opinion that the growth inhibition of the renal dwarf and the renal changes that occur in renal dwarfism present a congenital syndrome. In the development of renal rickets two factors probably assume an etiologic role, calcium deficiency and chronic acidosis.

**Cholesterol Metabolism in Vascular Diseases.**—On the basis of a comparison of the colorimetric and gravimetric methods for the determination of the cholesterol content, Kirehessner concludes that, if done carefully, the gravimetric method gives exact values, while he rejects the colorimetric method as too inaccurate. He considers a causal relation between hypercholesterolemia and hypertension unlikely, because he found no unequivocal increases in the cholesterol values in any of the various forms of hypertension. With few exceptions, however, the patients with hypertension show a disturbance in the ratio between free cholesterol and cholesterol ester, the free cholesterol is nearly always increased. The author describes experiments on rabbits. On the basis of clinical and experimental observations, he rejects the theory that the increased cholesterol content of the blood is the cause of hypertension, but he admits the occasional concurrence of hypercholesterolemia and hypertension.

**Production of Gastric Ulcers by Caffeine.**—Because caffeine stimulates the secretion of gastric juice, Hanke employed it for the experimental production of chronic ulcers in cats. For two months the animals were given almost daily subcutaneous injections of from 0.2 to 0.3 Gm of caffeine sodiosalicylate (in a 10 or 20 per cent solution). They were given their usual plentiful supply of food in the evening. The remnants of the food were removed early in the morning, so that, when the injection was made at noon, the cats had had no food or fluid for at least four hours. A new supply of food was not given until six hours after the injection. At the end of two months the stomachs of the cats showed chronic ulcers, the structure of which resembled closely that of human ulcers (leukocytic layer of exudate, layer of fibrinoid necrosis, layer of granulation tissue). The author assumes a primary peptic pathogenesis. He thinks that the ulcers develop as the result of the influence exerted by the excessive amount of acid gastric juice (secreted because of the caffeine injection) on the mucous membrane of the empty stomach. He calls attention to the possibility that caffeine may play a part in the pathogenesis and further development of peptic ulcers in human subjects.

**Changes in Blood Caused by Poisoning with Aniline.**—Gaeta describes the changes observed in the blood of rabbits that had been poisoned with parenterally administered aniline. He observed an intense and rapid reduction in erythrocytes running parallel with the severity of the poisoning, and a slight hypochromia with progressive decrease in the hemoglobin. The blood smears revealed anisochromia, anisocytosis, polychromatophilia and poikilocytosis. During the terminal stage there appeared orthochromatic and basophile erythroblasts in the circulating blood. It was never possible to demonstrate the presence of erythrocytes with basophile granules, or those endoglobular formations which other observers had noted in the erythrocytes of animals poisoned with substances forming methemoglobin. Vital staining revealed a constant increase in the erythrocytes with granular and thready substance, but it proved extremely difficult to demonstrate the presence or a percental increase of the erythrocytes with metachromatic granules. The white blood picture was hardly at all influenced, except that shortly before death, after the poison had caused

a severe cachexia, there was a pronounced leukocytosis. The examination of the bone marrow disclosed an intensive erythremic reaction with involvement of the leukopoietic as well as of the megakaryopoietic system. In some animals the bone marrow even showed the typical aspects of a myeloid metaplasia.

 Masked Myxedema E. Risak—p 821

**Artificial Respiration**—Jellinek calls attention to deficiencies in the usual methods of resuscitation, namely, to the fact that there is frequently neglect to pull the tongue of the victim forward so as to permit a free passage of air, and to the fact that by the compression of the thorax, which is the principal pressure, and also for the lung itself, is reduced or even nullified. The fact that the compression of the thorax sometimes produces results does not appear to the author as a valid argument against the danger inherent in this method. In discussing the first point of his criticism, that is, the failure to insure a free passage of air, he shows that some of the methods suggested for this are not suited for emergencies. He suggests a new method. He advises that the second and third fingers of the right or left hand of the victim be brought into the mouth so that their terminal phalanges press the tongue against the lower teeth, and that at the same time the fingers be pushed completely into the mouth. In order to keep them in this position the elbow has to be given support by tying it up. Not only respiratory fixation of the tongue leaves the air passage unhindered. In order to avoid the dangers involved in the compression or traction of the thorax the author suggests the following method. The victim is lying horizontally and on his back. A folded cloth, some paper or straw is placed under him in the region of the upper angles of the scapulae, thereby producing a free space between the shoulders and the surface of the patient is lying on. Then the tongue fixation is done in the manner described. Artificial respiration is done by grasping each shoulder with one hand in such a manner that the fingers rest on the external surface of the upper end of the arm and a quick pressure is released just as quickly. The same procedure is repeated after intervals of from one to two seconds. In discussing the effect on the thorax, the author points out that roentgenoscopy reveals that the described manipulation of the shoulders results in an extension of all three diameters of the thorax. Tests of the pressure conditions and manometric tests disclose the suction produced by the method, in fact, all tests prove that this new technic of artificial respiration produces an enlargement of the thorax and active inspiration.

**Rapid Diagnosis of Pregnancy**—Mandelstamm and Kaplan show that, if sexually mature mice which have been exposed to irradiation with red rays are employed in the hormone pregnancy test, the time required for its completion is only half of that required for the original Aschheim-Zondek test. They inject from 3 to 5 cc of detoxicated urine of a pregnant woman intravenously into the animals and from forty-eight to fifty hours later the characteristic blood dots can be seen in the ovaries of the animals without the aid of microscopic inspection. The irradiation with red rays permits a reduction in the number of experimental animals for each test to two or even one. The authors assert that the reliability of their modified method is equal to that of the original method. A great advantage of the method is the ease with which the experimental animals can be obtained because adult animals can be used, irrespective of the phase of the sex cycle. Moreover, the animals do not have to be killed and can be used for other experiments.

**Thallium Poisoning**—Klemperer relates the clinical history of a woman, aged 37, who was hospitalized from five to six weeks after her disorder had begun with vomiting and diarrhea. The woman related that in the last three or four weeks she had had pains in the lower extremities, particularly in the thighs. At first she was still able to walk but later there was formication, her toes felt dead and the pains became so severe that she was unable to walk. She felt formication also in the left arm and vomited after eating. She lost all the hair of her head, and her scalp was painful. The severe pains resulted in insomnia. At first there was no clue as to what could have caused the disturbance, but finally the patient recalled that shortly before the first symptoms appeared she had tried to poison her dog (old and blind), by putting a poisonous paste in his soup. She ate the same kind of soup and since the two plates looked alike she must have mistaken the one for the other, for nothing happened to the dog. The author gives a detailed description of the clinical course. The patient presented the aspects of a polyneuropathy with frequent recurrences. There were several unusual aspects, which from the typical symptomatology of thallium poisoning, supercilary hair growth was not impaired in the lateral and more curly. Another not quite typical symptom was dilatation of the pupils. They reacted to light promptly but slightly and became dilated again immediately, so that they presented the aspects of a lippus. Most interesting were the motor disturbances of the upper extremities. When the woman held the arms forward a tremor was noticeable like that which is observed in alcoholism or lead poisoning. Superimposed on this tremor, there were peculiar pendulum-like movements of the arms. The patient was unable to suppress these movements when she tried to hold the arms quiet, but when she performed active movements they disappeared. The nature of the lesion that caused these symptoms can only be conjectured.

**Substance Producing Allen-Doisy Test**—Engel succeeded in demonstrating in the blood a substance capable of producing a positive Allen-Doisy test. However, the substance influences neither the uterus nor the male genitalia. It lacks gonadotropic influence. The substance is obtained in a similar manner as is the estrogenic substance of the pineal body (which it resembles also in its action), by alkaline-aqueous extraction from acetone dry powder. The blood of younger men contains the substance in larger quantities than does that of older men. In women the opposite condition seems to obtain, that in both sexes there are so many exceptions from this rule that a valid generalization is impossible. Many factors seem to indicate that the substance is identical with that of the pineal body but because the substance is more rapidly than is the case in the extracts of the pineal body, this conclusion cannot be drawn with absolute certainty. Of course it is possible that the pineal body contains also an inhibiting substance. The concentration is much less in the blood than in the pineal body.
